30  
31 **Abstract** The microlocalisation of Cu was examined in the leaves of white lupin and  
32  
33 soybean grown hydroponically in the presence of 1.6 or 192  $\mu\text{M}$  Cu, along with its  
34  
35 effect on leaf morphology, (ultra)structure and the antioxidative response. The 192  $\mu\text{M}$   
36  
37 dose led to a reduction in the total leaf area and leaf thickness in both species, although  
38  
39 more strongly so in white lupin. In the latter species it was also associated with smaller  
40  
41 spongy parenchyma cells, and smaller spaces between them, while in the soybean it  
42  
43 more strongly reduced the size of the palisade parenchyma and epidermal cells. Energy-  
44  
45 dispersive X-ray microanalysis showed that under Cu excess the metal was mainly  
46  
47 localised inside the spongy parenchyma cells of the white lupin leaves, and in the lower  
48  
49 epidermis cell walls in those of the soybean. Cu excess also promoted ultrastructural  
50  
51 chloroplast alterations, reducing the photosynthetic capacity index and the green area of  
52  
53 the leaves, especially in the soybean. Despite this, the soybean appeared to be more  
54  
55 tolerant to Cu excess than the white lupin, perhaps because i) soybean accumulates  
56  
57  
58  
59  
60

1  
2  
3 smaller amounts of Cu in the leaves, ii) of the microlocalisation of Cu in the cell walls  
4  
5 iii) and because of greater induced thiol, superoxide dismutase and catalase activities  
6  
7 investing it with a better antioxidative response.

## Introduction

High copper concentrations have been recorded in some natural soils, although Cu toxicity is more commonly a problem of those polluted by Cu-rich pig and poultry slurries, fertilizers and fungicides, industrial and urban activities, metal mining and processing, and waste disposal (Yruela 2009). While Cu is an essential element for plant growth and development, it is highly toxic to plants at concentrations of  $> 20 \mu\text{g g}^{-1}$  dry weight (DW) (Marschner 1995). In general, Cu excess inhibits seed germination and plant growth by interfering with respiration, nitrogen and protein metabolism, and photosynthesis (Yruela 2009), and by causing the overproduction of reactive oxygen species (ROS). Some plants possess mechanisms - enzymatic or non-enzymatic scavenging systems - whose function it is to prevent the oxidative damage caused by ROS (Sharma and Dietz 2008).

The indirect consequence of changes in metabolism and/or signal transduction caused by toxic metals, as well as the direct interaction of the latter with structural components, can cause damage at the cellular, tissular and organ levels in plants (Barceló and Poschenrieder 2004). The visible symptoms of toxicity include structural/ultrastructural abnormalities, leaf chlorosis and necrosis, stem shortening, browning, and altered root morphology (Marschner 1995). The actual problems encountered are dependent on the species and ecotype in question, the concentration of the toxic metal present, the exposure time, and the properties of the soil (Yruela 2009). Certainly, marked differences in Cu tolerance have been observed in different plants.

While *Arabidopsis halleri* (Yruela 2009), *Elsholtzia haichowensis* (Lou et al. 2004), *Elsholtzia splendens* (Shi et al. 2004), *Phragmites australis* (Ali et al. 2002), *Silene*

1  
2  
3 *vulgaris* and *Thalpi caerulescens* (Yruela, 2009) can tolerate excess Cu to some extent,  
4  
5 *Oryza sativa* (Jones 1998) and *Zea Mays* are much more sensitive (Ali et al. 2002).  
6

7  
8 White lupin (*Lupinus albus* L.) is a temperate grain legume of great agronomic  
9 potential given its high seed protein content and positive effect on soil fertility. The  
10 ability of white lupin to survive in soils of low pH and low nutrient availability  
11 (Fernández-Pascual et al. 2007), and the species' intrinsic biomass production and  
12 relative tolerance to trace elements such as As, Hg and Cd (Vázquez et al. 2009;  
13 Esteban et al. 2008; Zornoza et al. 2002), suggest it to be a suitable species for use in  
14 the remediation of contaminated soils. Soybean (*Glycine max* L.), however, is the most  
15 economically important of all grain legumes. In some countries it is a major protein  
16 source, and is sometimes grown on As- and Cu-contaminated soils (e.g., in China). It is  
17 also used as a model system for legume–*Rhizobium* research (Reichman 2007).

28

29  
30 There are few studies that relate Cu microlocalisation to plant tolerance of this  
31 metal. However, the pattern of Cu microlocalisation in cells and tissues may provide  
32 insights into tolerance mechanisms, and might help explain differences in tolerance  
33 between species. To test this hypothesis, the microlocalisation of Cu was studied in the  
34 leaves of white lupin and soybean by energy-dispersive X-ray microanalysis. The  
35 accompanying (ultra)structural, morphological and physiological alterations, as well as  
36 the enzymatic (APX, CAT and SOD) and non-enzymatic (MDA and –SH) antioxidant  
37 response of the plants, were also examined.

## 49 **Materials and methods**

### 50 51 52 53 54 Growth conditions and Cu treatments

55  
56  
57  
58  
59  
60

1  
2  
3 White lupin cv. Marta and soybean cv. Williams seeds were surface-sterilised in 10%  
4 v/v sodium hypochlorite for 15 min, rinsed thoroughly with deionised water and  
5  
6  
7 germinated on water-moistened filter paper in the dark at 28°C for 3 days. The seedlings  
8  
9  
10 obtained were placed in plastic Riviera pots (three seedlings to each pot) containing 2 L  
11  
12 of perlite in the upper compartment and 0.75 L of nutrient solution in the lower. The  
13  
14 composition of the nutrient solution, the inoculation of the plants with *Bradyrhizobium*,  
15  
16 and the plant growth conditions were similar to those reported in earlier work (Sánchez-  
17  
18 Pardo et al. 2012). These young plants were grown in a controlled environment chamber  
19  
20 under the following night/day conditions: temperature 20/25°C, photoperiod 11/13 h,  
21  
22 and relative humidity 60/40%. The photon flux density during the light periods was 520  
23  
24  $\mu\text{mol m}^{-2} \text{s}^{-1}$ . Ten days after sowing, the plants were subjected to one of two Cu  
25  
26 treatments (1.6 or 192  $\mu\text{M}$   $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ) with four replicates, following a randomised  
27  
28 block design. The very high 192  $\mu\text{M}$  dose was chosen to ensure that sufficient quantities  
29  
30 of Cu would accumulate and be detectable in the different leaf compartments.  
31  
32

33  
34 After 35 days the plants were divided into leaves, stems and roots, and weighed.  
35  
36 They were then washed thoroughly with tap water three times, and then again with  
37  
38 deionised water three times. One gram (fresh weight [FW]) of total homogenised leaves  
39  
40 per plant were frozen in liquid  $\text{N}_2$  and stored at  $-76^\circ\text{C}$  until analysis. The remaining leaf  
41  
42 material was dried at  $80^\circ\text{C}$  for 3 days until a constant dry weight (DW) was reached.  
43  
44 These dry samples were homogenised and used for element determination.  
45  
46  
47

#### 48 49 Copper and Fe concentrations

50  
51  
52 The concentration of Cu and Fe in leaves was determined by digesting 20 mg DW of  
53  
54 homogenised samples with a mixture of  $\text{HNO}_3$ : $\text{H}_2\text{O}_2$ : $\text{H}_2\text{O}$  (3:2:10, v:v:v) for 30 min at  
55  
56  $125^\circ\text{C}$  under a pressure of 1.5 kPa (Lozano-Rodríguez et al. 1995). Cu and Fe  
57  
58  
59  
60

1  
2  
3 concentrations were then determined by atomic absorption spectrophotometry (Perkin-  
4 Elmer Analyst 800).  
5  
6

#### 7 8 Electron microscopy and energy-dispersive X-ray microanalysis 9

10  
11 Small pieces (1 mm<sup>2</sup>) of fresh leaf from the 1.6 and 192 µM Cu-treated plants, selected  
12 at comparable stages of development, were mounted with adhesive (Gurr®, OCT, BDH,  
13 Poole, UK) on aluminium stubs. They were then cryofixed in slush nitrogen (-196°C)  
14 and cryotransferred to a vacuum chamber at -180°C to be fractured using a cooled  
15 stainless steel spike. After placing them in a Zeiss DSM 960 digital scanning electron  
16 microscope (Oberkochen, Germany) the samples were subjected to superficial etching  
17 under vacuum (-90°C, 120 s, 2 kV) and gold coated. Fractured leaf material was  
18 observed at low temperature employing secondary and back-scattered electrons.  
19 Energy-dispersive X-ray microanalysis (EDXMA) was performed in conjunction with  
20 low temperature scanning electron microscopy (LTSEM) using a Pentafllet apparatus  
21 (Pentafllet, Oxford, UK) at a resolution of 133 eV. Only smooth surfaces were taken for  
22 microanalysis, following the recommendations of Hess (1980). Semi-quantitative  
23 element analysis was performed using standard ZAF (atomic number, absorption and  
24 fluorescence) correction procedures employing Link Isis 3.2 software (Link Isis, Oxford,  
25 UK).  
26

40  
41  
42  
43  
44  
45

#### 46 Light and electron microscopy 47

48  
49 Small pieces of fresh leaf (1 mm<sup>2</sup>) from the 1.6 and 192 µM Cu-treated plants, selected  
50 at comparable stages of development, were fixed in 2.5% (v/v) glutaraldehyde in 50  
51 mM Na-cacodylate buffer containing sucrose (Fedorova et al. 2005), pH 7.4, and  
52 vacuum-infiltrated before dehydrating through a graded ethanol series. They were then  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 embedded in LR White Resin (London Resin, London, UK) in gelatine capsules,  
4  
5 according to de Lorenzo et al. (1998). Polymerisation was allowed to occur for 24 h at  
6  
7 60°C. Sections 1 µm-thick were prepared for light microscopy, and 70 nm-thick for  
8  
9 electron microscopy, using a Reicher Ultracut S ultramicrotome fitted with a diamond  
10  
11 knife. The semithick sections were stained with 1% (w/v) toluidine blue in aqueous  
12  
13 sodium borate for direct examination using a Zeiss Axiophot photomicroscope. The  
14  
15 ultrathin sections were post-stained with lead citrate and examined using a STEM LEO  
16  
17 910 electron microscope at an accelerating voltage of 80 kV.  
18  
19

#### 20 21 22 Stress indicators and antioxidant enzymes 23

24  
25 The concentrations of malondialdehyde (MDA) (a cytotoxic product of lipid  
26  
27 peroxidation normally considered the major 2-thiobarbituric acid-reacting compound)  
28  
29 and total thiols (-SH) were examined in samples of leaves homogenised to a fine  
30  
31 powder in liquid N<sub>2</sub> using an ice-cooled mortar and pestle. They were then assayed as  
32  
33 described by Esteban et al. (2008).  
34  
35

36  
37 Antioxidant enzyme activity was determined by homogenising 100 mg FW of  
38  
39 leaves in 1.5 mL of ice-cooled phosphate buffer (50 mM, pH 7.0, containing 1 mM  
40  
41 ethylenediamine tetra-acetic acid (EDTA) and 1% w/v insoluble polyvinylpyrrolidone)  
42  
43 and passing the solution through four layers of cheese cloth. The extract obtained was  
44  
45 centrifuged at 15,000 × g for 15 min at 4°C. The supernatant was used to measure the  
46  
47 activities of superoxide dismutase (SOD), ascorbate peroxidase (APX) and catalase  
48  
49 (CAT). The protein content of the supernatant was measured according to Lowry et al.  
50  
51 (1951).  
52  
53

54  
55 SOD (EC 1.1.5.1.1) activity was assayed using the method of Srivastava et al.  
56  
57 (2006), measuring its ability to inhibit the photochemical reduction of nitro-blue  
58  
59  
60

1  
2  
3 tetrazolium (NBT). The 3 mL reaction mixture contained 40 mM phosphate buffer (pH  
4  
5 7.8), 13 mM methionine, 75  $\mu\text{M}$  NBT, 2  $\mu\text{M}$  riboflavin, 0.1 mM EDTA and a suitable  
6  
7 aliquot of enzyme extract. The test tubes were shaken and placed 30 cm below a 15 W  
8  
9 fluorescent lamp. Absorbance was then measured at 560 nm. The activity of SOD was  
10  
11 expressed as units  $\text{mg}^{-1}$  protein. One unit of activity was defined as the amount of  
12  
13 protein required to reduce NBT under light to 50% of the initial concentration.  
14  
15

16  
17 APX (EC 1.11.1.11) activity was measured by estimating the rate of ascorbate  
18  
19 oxidation (extinction coefficient  $2.8 \text{ mM}^{-1} \text{ cm}^{-1}$ ). The 3 mL reaction mixture contained  
20  
21 50 mM phosphate buffer (pH 7.0), 0.1 mM  $\text{H}_2\text{O}_2$ , 0.5 mM sodium ascorbate, 0.1 mM  
22  
23 EDTA and a suitable aliquot of enzyme extract. The change in absorbance was  
24  
25 monitored at 290 nm (Srivastava et al. 2006) and the enzyme activity expressed as units  
26  
27  $\text{mg}^{-1}$  protein.  
28  
29

30  
31 CAT (EC 1.11.1.6) activity was assayed by measuring the decomposition of  
32  
33  $\text{H}_2\text{O}_2$ . Enzyme extract (100  $\mu\text{L}$ ) was added to the reaction mixture containing 1 mL  
34  
35 phosphate buffer solution (50 mM, pH 7.0) and 0.1%  $\text{H}_2\text{O}_2$ . The reduction in the  
36  
37 absorbance at 240 nm was then recorded and the enzyme activity calculated using an  
38  
39 extinction coefficient of  $0.04 \text{ mM}^{-1} \text{ cm}^{-1}$ . One unit of CAT activity was defined as the  
40  
41 amount required to decompose 1  $\mu\text{mol}$  of  $\text{H}_2\text{O}_2 \text{ min}^{-1} \text{ mg}^{-1}$  protein under the assay  
42  
43 conditions (Chen et al. 2009).  
44  
45

46  
47 Morphological and physiological leaf variables, and statistical analyses

48  
49 The calculation of leaf thickness was performed using ImageJ 1.45 software. Leaf area  
50  
51 (LA), the photosynthetic capacity index (PCI) and the green, yellow and red leaf areas  
52  
53 were calculated using optically scanned leaf samples and Foliárea software (Muñoz-  
54  
55 Guerra 2002).  
56  
57  
58  
59  
60

1  
2  
3 The data presented are the means  $\pm$  standard errors (S.E.) of four independent  
4 replicates. To ensure that the assumptions for statistical analysis were fulfilled, the  
5 equality of variances and the normality of the data were tested. Differences between  
6  
7 equality of variances and the normality of the data were tested. Differences between  
8  
9 means for each variable were tested for significance by one-way ANOVA. Means were  
10 compared using the least significant difference test. Significance was set at  $P < 0.05$ . All  
11 calculations were performed using IBM SPSS v.19.0 software.  
12  
13  
14  
15  
16

## 17 Results

### 20 Total Cu and Fe concentrations and Cu microlocalisation in leaves

21  
22  
23 Table 1 shows the leaf Cu and Fe concentrations for the white lupin and soybean plants  
24 grown under the 1.6 and 192  $\mu\text{M}$  Cu conditions. The concentration of Cu in the leaves  
25 of the white lupin and soybean 192  $\mu\text{M}$  Cu-treated plants was 13.5 and 9.8 times that  
26 recorded in the control (1.6  $\mu\text{M}$  plants) respectively. In contrast, the 192  $\mu\text{M}$  Cu  
27 treatment significantly reduced the leaf concentration of Fe – by 91% in white lupin and  
28  
29 63% in soybean.  
30  
31  
32  
33  
34  
35  
36  
37  
38  
39

40  
41 Figure 1 shows the EDXMA results for the leaves of white lupin and soybean  
42 plants exposed to the 1.6 and 192  $\mu\text{M}$  Cu treatments. In white lupin, the latter treatment  
43 increased the Cu signal from the cytoplasm-vacuole of the spongy parenchyma cells to  
44  
45 10 times that of the control 1.6  $\mu\text{M}$  Cu plants. The signal from the cell walls of the  
46 lower epidermal cells increased 1.6 times. In the same species, a decreasing Cu gradient  
47 was observed between the cell walls of the lower epidermal cells to those of the upper  
48  
49 epidermis (Fig. 1c).  
50  
51

55  
56  
57  
58  
59  
60

1  
2  
3 In the soybean leaves, exposure to the 192  $\mu\text{M}$  Cu conditions increased the Cu  
4 signal from the cytoplasm-vacuole of the lower epidermal cells to 1.4 times that of the  
5 controls. In the cell walls of the palisade parenchyma the signal increased to 1.6 times  
6 that recorded in the controls, while in the lower epidermal cells it increased 3.7 times. In  
7 contrast, reductions were seen in the Cu signal from the cytoplasm-vacuole of the  
8 palisade parenchyma cells (28%), as well as from the walls of the upper epidermal cells  
9 (23%). No changes were seen in other tissues (Figs. 1b, d). The leaves of plants  
10 subjected to the 1.6  $\mu\text{M}$  Cu treatment showed no clear pattern of Cu distribution, while  
11 those treated with 192  $\mu\text{M}$  dose showed a decreasing gradient from the lower epidermal  
12 cells towards the cell walls of the upper epidermal cells (Figs. 1b, d).

#### 25 26 Leaf variables

27  
28  
29 Table 2 shows the leaf biomass, LA, LT, number of leaves (LN), PCI, and the green,  
30 yellow and red leaf areas for white lupin and soybean plants grown under the 1.6 and  
31 192  $\mu\text{M}$  Cu conditions. The high dose reduced the leaf biomass by 77% in white lupin  
32 and 69% in soybean. In white lupin plants exposed to the 192  $\mu\text{M}$  Cu treatment, the LA,  
33 LT, LN and PCI were reduced by 68%, 29%, 47% and 36% respectively with respect to  
34 the controls, while the yellow leaf area increased significantly (10 times). However, no  
35 differences were seen between the treatments in terms of green and red leaf area. In the  
36 leaves of the 192  $\mu\text{M}$  Cu-treated soybean plants, the LA, LT and LN, the PCI and the  
37 green leaf area were reduced significantly by 64%, 27%, 29%, 77% and 29%  
38 respectively compared to the controls. In contrast, the high Cu dose increased the  
39 yellow and red leaf areas 11 and 7.5 times respectively.

## Leaf and chloroplast (ultra)structure

Figures 2 and 3 show the effects of the 1.6 and 192  $\mu\text{M}$  Cu treatments on the structure of the white lupin and soybean leaves, as determined by light microscopy. The leaves of the white lupin plants showed a well-organised structure after both treatments (Fig. 2a, b, c). However, the 192  $\mu\text{M}$  treatment leaves were thinner, and the mesophyll cells and intercellular spaces were smaller than in the controls; this was more apparent in the spongy parenchyma than the palisade parenchyma (Fig. 2b). Further, the spongy and palisade parenchyma cells of the 192  $\mu\text{M}$  Cu-treated plants showed a reduction in the number and size of chloroplasts, and of large starch granules (Fig. 2d). In some cells of the palisade parenchyma, the chloroplasts appeared more distant from the cell wall, a likely consequence of the separation of the latter from the plasma membrane (Figs. 2e, f). In soybean, the leaves of the 192  $\mu\text{M}$  Cu-treated plants were slightly thinner and the palisade parenchyma cells and abaxial and adaxial epidermal cells were smaller (Figs. 3a, b). The spongy parenchyma cells were not affected. The packing of both types of mesophyll cell also remained unaffected (Figs. 3b, c, d).

Figures 4 and 5 show the effects of the 192  $\mu\text{M}$  treatment on the ultrastructure of the white lupin and soybean leaves. Figure 4a shows the ultrastructure of a chloroplast from the leaf of a control white lupin plant; note the parallel arrangement of the grana and intergrana with respect to the chloroplast axis. White lupin plants treated with 192  $\mu\text{M}$  Cu showed three types of chloroplast in their leaves: 1) approximately a 40% had a single starch granule, an unaffected thylakoid structure, but a very electron-dense stroma; such chloroplasts were slightly distant from the cell wall (Fig. 4b); 2) those with more than two starch granules and showing incipient changes in the ultrastructure of the grana and intergrana, plus a loss of their normal parallel alignment with the main axis

1  
2  
3 (40%); these also showed a highly electron-dense stroma, a separation of chloroplast  
4 membrane (indicated by arrow) and a greater distance between the chloroplast  
5 membrane and cell wall (Fig. 4c); and 3) chloroplasts completely filled with starch, with  
6 a totally disorganized thylakoid structure, and showing clear signs of degradation  
7 (major deteriorations in the mitochondria [Fig. 4d] and cytoplasmic senescence vesicles  
8 [Fig. 4c, arrowheads] were also seen in lesser extent [20%]).  
9  
10  
11  
12  
13  
14  
15

16 The mesophyll cells of the 192  $\mu\text{M}$  Cu-treated soybean plants also showed an  
17 increase in the number of starch granules (between 2-7, mean = 5). In addition, they  
18 showed bulging of the chloroplast membrane and a loss of the parallel orientation of the  
19 grana and intergrana with respect to the chloroplast axis (Fig. 5b). The number of grana  
20 was reduced, as was the number of thylakoids per granum. Some thylakoids became  
21 swollen, leading to the appearance of plastoglobuli (Fig. 5c). Many were seen in the  
22 interior of the chloroplasts; these sign signs of early senescence are characteristic of  
23 degraded tissue (Fig. 5c, d).

#### 34 Stress indicators and antioxidant enzymes

35  
36  
37  
38 Table 3 shows the MDA and total SH contents, as well as the SOD, APX and CAT  
39 activities of the leaves of white lupin and soybean plants exposed to the 1.6 and 192  $\mu\text{M}$   
40 Cu treatments. The total SH content of the leaves of the white lupin plants grown under  
41 the 192  $\mu\text{M}$  Cu conditions did not vary with respect to the 1.6  $\mu\text{M}$  Cu treatment.  
42  
43 However, in soybean, it was 1.6 times that recorded in the corresponding control plants.  
44  
45 The concentrations of MDA in the leaves of both types of plant grown under the 192

2  
3 Exposure to the 192  $\mu\text{M}$  Cu conditions reduced the activities of SOD and CAT  
4 by 35% and 45% in the white lupin leaves. However, no differences were seen between  
5 the treatments in terms of APX activity. The activities of SOD and CAT in the leaves of  
6 the 192  $\mu\text{M}$  Cu-treated soybean plants increased to 0.9 and 2.5 times those of the  
7 control plants, while the activity of APX was significantly reduced.

### 19 Discussion

20 In many sensitive species, Cu excess inhibits plant growth when leaf concentrations  
21 reach 15-20 mg Cu  $\text{kg}^{-1}$  DW. However, for most plants, Cu toxicity symptoms appear  
22 when leaf concentrations reach around 30 mg Cu  $\text{kg}^{-1}$  DW (Marschner 1995). In the  
23 present study, the concentration of Cu in the leaves increased in plants subjected to the  
24 high Cu dose, with the white lupin leaves accumulating about twice that of the soybean  
25 (Table 1). Indeed, the total Cu concentrations found in the leaves of both species fell  
26 within the toxicity range (Reuter and Robinson 1997).  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 The accumulation of high Cu levels in leaf tissues can cause morphological and  
37 structural disorders, affect many physiological processes, inhibit growth, and sometimes  
38 even hasten the death of a plant (Marschner 1995); it is well known that Cu excess can  
39 inhibit cell elongation and cell division (Panou-Filothou and Bosabalidis 2004). The  
40 cells of the leaves of bean plants exposed to toxic concentrations of Cu are reported to  
41 be smaller (Kasim 2005). This has been attributed to a reduction in the elasticity of the  
42 cell walls caused by the irreversible inhibition of proteins that regulate this feature  
43 (Kasim 2005). In the present study, reductions in the thickness of soybean and white  
44 lupin leaves were observed under Cu excess. In the white lupin, this reduction seems to  
45 be promoted by a decline in the size of the mesophyll cells (mainly of the spongy  
46  
47

1  
2  
3 parenchyma) and the spaces between them (Fig. 2). In soybean, the epidermis and  
4  
5 palisade parenchyma cells showed reduced volumes (Fig. 3). The opposite effect has  
6  
7 been observed in oregano leaves grown under Cu excess, due to an increase in the  
8  
9 number of mesophyll cells and their volume (Panou-Filothéou et al. 2001). In turn,  
10  
11 excess Cu adversely affected the LA and LN in both crops studied, although the  
12  
13 reduction was most pronounced in white lupin (Table 2). Elevated levels of Cu have  
14  
15 been associated with similar outcomes in cucumber (Alaoui-Sossé et al. 2004), oregano  
16  
17 (Panou-Filothéou et al. 2001) and wheat (Cook et al. 1997).  
18  
19

20  
21 In the present work, the leaf tissues most affected were those that accumulated  
22  
23 larger amounts of Cu. In white lupin, the excess Cu was mainly localised in the  
24  
25 cytoplasm-vacuole of the spongy parenchyma cells, whereas in the soybean leaves it  
26  
27 was mainly located in the cell walls of the leaf abaxial epidermal cells (Fig. 3). Other  
28  
29 authors have found Cu to be mainly localised in the upper epidermis and trichomes of  
30  
31 the abaxial epidermis in *Cannabis sativa* leaves (Arru et al. 2004), and in the vascular  
32  
33 tissues of *Avicennia marina* (MacFarlane and Burchett 2000) and *Elsholtzia splendens*  
34  
35 (Shi et al. 2004). The microlocalisation of heavy metals in cells and tissues provides  
36  
37 insight into the possible mechanisms of detoxification, and therefore of tolerance: the  
38  
39 outermost tissues and cell walls would appear to act as a barrier against its harmful  
40  
41 effects. The preferential accumulation of heavy metals in the epidermis would help to  
42  
43 protect mesophyll cells from the buildup and toxicity of metals and maintain the  
44  
45 functionality of mesophyll cells over a wide range of metal concentrations in the leaves  
46  
47 (Küpper et al. 1999).  
48  
49  
50

51  
52 Alterations in chloroplast structure have been reported in some plants under Cu  
53  
54 excess, such as rice (Lidon and Henriques 1993), bean (Maksymiec et al. 1994), wheat  
55  
56 (Quartacci et al. 2000) and oregano (Panou-Filothéou et al. 2001). In the present work,  
57  
58  
59  
60

1  
2  
3 both white lupin and soybean showed changes in the structure of the thylakoids,  
4 detachment and/or loss of integrity of the chloroplast membrane, and a degradation of  
5 grana stacking and the stroma (Figs. 4, 5). A swelling of the thylakoids and an increase  
6 in the number of plastoglobuli were also observed in the soybean plants (Fig. 5). It  
7 seems that soybean chloroplasts are more affected by Cu excess than those of white  
8 lupin.  
9

10  
11 According to Maksymiec et al. (1994), Cu interferes with the biosynthesis of the  
12 photosynthetic machinery, modifying the pigment and protein composition of the  
13 photosynthetic membranes. Low chlorophyll contents and the inhibition of  
14 photosynthetic activity have also been observed in the leaves of several species exposed  
15 to Cu excess (Yruela 2009). The opposite effect has been reported in Cu-tolerant plants  
16 (Borghini et al. 2008). In the present work, Cu excess promoted a reduction of the PCI  
17 and the green leaf area, more so in the soybean than in the white lupin plants (Table 2).  
18 The reduction in photosynthetic activity may be due to a fall in the biosynthesis of  
19 chlorophyll, caused by the destruction of the internal structure of the chloroplast and  
20 thylakoid membrane damage (Quartacci et al. 2000). Päsikkä et al. (2002) attributed the  
21 reduction of the chlorophyll content to a Cu-induced Fe deficiency. In the present work,  
22 Cu excess caused an intense reduction in the leaf Fe concentration in both species, more  
23 so in white lupin than in soybean (Table 1). In both legumes, the Fe concentrations  
24 recorded can be considered deficient (Reuter and Robinson 1997). Nevertheless, the  
25 white lupin leaves still had a higher Fe concentration under Cu stress than did the  
26 soybean plants. Soybean would seem to be sensitive to Fe deficiency. This may explain  
27 why the photosynthetic activity and chloroplast structure were more affected than in the  
28 white lupin.

1  
2  
3 Copper excess catalyze the formation of hydroxyl radicals ( $\text{OH}\cdot$ ) from the non-  
4  
5 enzymatic chemical reaction between superoxide ( $\text{O}_2^{\cdot-}$ ) and  $\text{H}_2\text{O}_2$  (Haber-Weiss  
6  
7 reaction). These cause lipid peroxidation (Navari-Izzo and Quartacci 2001), damage to  
8  
9 the photosynthetic apparatus (Vajpayee et al. 2005), and may also catalyze the  
10  
11 degradation of proteins through oxidative modifications and increased proteolytic  
12  
13 activity (Romero-Puertas et al. 2002). The degree of damage suffered by cells depends  
14  
15 on the rate of ROS formation and the efficiency and capacity of their detoxification and  
16  
17 repair mechanisms. The MDA concentration provides an index of lipid peroxidation and,  
18  
19 therefore, of oxidative stress. In the present work, Cu excess led to increased leaf MDA  
20  
21 concentrations in both species, although more strongly in soybean (Table 3). The  
22  
23 differences between species might be attributable to the increased number of  
24  
25 plastoglobuli observed in the soybean plants only.  
26  
27  
28

29  
30 Antioxidants are molecules that inhibit or slow down the oxidation of other  
31  
32 molecules, thus stopping the propagation of oxidative chain reactions (Navari-Izzo and  
33  
34 Quartacci 2001). Thiol groups play an important role in the cytoplasmic detoxification  
35  
36 defence mechanism against heavy metals, but they are also required to counteract the  
37  
38 harmful effects of oxidative stress (Noctor and Foller 1998). Plants can respond to  
39  
40 oxidative stress by stimulating enzymatic antioxidative systems. The effects of Cu on  
41  
42 the activity of antioxidant enzymes and the involvement of these enzymes in the  
43  
44 defence of plant tissues against metal-induced damage remain unclear, with differences  
45  
46 seen between plant species and tissues, and depending on the concentration and duration  
47  
48 of exposure (Chamseddine et al. 2009). Yurekli and Porgali (2006) showed that, in  
49  
50 *Phaseolus vulgaris*, both low and high concentrations of Cu lead to an increase in CAT  
51  
52 and SOD activities after Cu excess. Chaoui and El Ferjani (2005), in contrast, reported  
53  
54 that the exposure of pea plants to 20  $\mu\text{M}$  Cu had no effect on the activity of these  
55  
56  
57  
58  
59  
60

1  
2  
3 enzymes, although the supply of 100  $\mu\text{M}$  Cu did reduce it. In the present soybean plants,  
4  
5 the enzymatic and non-enzymatic scavenging systems were enhanced under Cu excess,  
6  
7 whereas antioxidant activity was depressed in the white lupin plants (Table 3). A  
8  
9 reduction in antioxidant enzyme activity would result in the accumulation of reactive  
10  
11 oxygen species and the recorded reductions in photosynthetic pigments and activity.  
12  
13 The scavenging function of both studied enzymes appears to have been impaired by the  
14  
15 prolonged period of severe stress (Chamseddine et al. 2009). In addition different  
16  
17 enzymatic antioxidant responses shown by the legumes studied may be due to  
18  
19 differences in affinities for  $\text{H}_2\text{O}_2$  between APX and CAT. Mittler (2002), proposed that  
20  
21 “two-way defence systems” might be involved, suggesting that ROS could be  
22  
23 eliminated through the SOD–CAT pathway or by the ascorbate–glutathione cycle, both  
24  
25 of which are considered ROS-scavenging systems”.

26  
27  
28  
29 In conclusion, Cu excess affects chloroplast ultrastructure and photosynthetic  
30  
31 capacity in both soybean and white lupin legumes, especially in the former. This could  
32  
33 be due to reduced Fe contents, particularly in the soybean leaves. Despite this, the  
34  
35 soybean plants appeared to be more tolerant to Cu excess than the white lupin plants, as  
36  
37 shown by their smaller reduction in biomass and the less intense effects on leaf  
38  
39 morphology and structure. This could be due to soybean: i) transporting smaller  
40  
41 amounts of Cu to the leaves, reducing its accumulation in these organs; ii) the different  
42  
43 sites of Cu microlocalisation - soybean leaves localised Cu in the walls of the lower  
44  
45 epidermis cells while the white lupin plants accumulated Cu mainly inside of the  
46  
47 spongy parenchyma cells, and iii) the induction of a better antioxidative response.  
48  
49 Finally, the structural alterations observed seem to bear a relationship with Cu  
50  
51 microlocalisation; the tissues most affected were those that localised the largest  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 quantities of Cu. It would therefore seem that Cu microlocalisation is an important  
4  
5 factor to consider when assessing the response of plants to Cu excess.  
6

**Figure captions**

**Fig. 1** EDXMA-determined Cu localisation in transverse sections of leaves of 1.6 and 192  $\mu\text{M}$  Cu-treated plants, viewed by LTSEM. Values are expressed as percentages of the total signal. Data are means  $\pm$  S.E. ( $n = 4$ ). Different letters to the right of the bars indicate significant differences between Cu treatments ( $P < 0.05$ ).

**Fig. 2** Photomicrographs of white lupin leaves from plants grown with 1.6  $\mu\text{M}$  (**a,c**) or 192  $\mu\text{M}$  Cu (**b, d, e, f**). Cl: chloroplast, LE: lower epidermis, PP: palisade parenchyma, SP: spongy parenchyma, S: starch, UE: upper epidermis, VB: vascular bundle

**Fig. 3** Photomicrographs of soybean leaves from plants grown with 1.6  $\mu\text{M}$  (**a, c**) or 192  $\mu\text{M}$  (**b, d**) Cu. Cl: chloroplast, LE: lower epidermis, PP: palisade parenchyma, SP: spongy parenchyma, S: starch, UE: upper epidermis, VB: vascular bundle

**Fig. 4** Electron micrographs of white lupin leaves from plants grown with 1.6  $\mu\text{M}$  (**a**) or 192  $\mu\text{M}$  (**b-d**) Cu. C: cytosol, Cl: chloroplast, CM: chloroplast membrane, CW: cell wall, G: grana, IG: intergrana, M: mitochondria, Pe: peroxisome, S: starch, T: tonoplast, V: vacuole

**Fig. 5** Electron micrographs of soybean leaves from plants grown with 1.6  $\mu\text{M}$  (**a**) and 192  $\mu\text{M}$  (**b-d**) Cu. C: cytosol, Cl: chloroplast, CW: cell wall, ER: endoplasmic reticulum, G: grana, IG: intergrana, N: nucleus, P: plasmalemma, Pe: peroxisome, PG: plastoglobuli, S: starch

**Table 1** Concentrations of Cu and Fe ( $\text{mg kg}^{-1}$  DW) in the leaves of white lupin and soybean grown for 35 days with 1.6 or 192  $\mu\text{M}$  Cu treatments. Data are means  $\pm$  S.E. ( $n = 4$ ). Values in the same row followed by different letters differ significantly ( $P < 0.05$ ).
