• Capital latin letters ($M, N, P \ldots$) refers to five dimensional indices

• Greek letters ($\mu, \nu, \rho \ldots$) will refer to four dimensional indices

• Lower case from the end of the alphabet latin letters ($i, j, k \ldots$) refers to three dimensional indices

• Lower case from the beginning of the alphabet latin letters ($a, b, c \ldots$) refers to two dimensional indices

• $g_{MN}$ is the five dimensional metric with signature $(+, -, +, +, +)$ and $g$ its determinant

• $h_{\mu\nu}$ the induced four dimensional boundary metric with signature $(-, +, +, +)$ and $h$ its determinant

• The epsilon density is defined in terms of the Levi-Civita symbol as

  $$\varepsilon_{MNPQR} = \sqrt{-g} \varepsilon(MNPQR)$$

  $$\varepsilon(r0123) = 1$$

  The Christoffel symbols, Riemann tensor and extrinsic curvature are given by

  $$\Gamma_{NP}^M = \frac{1}{2} g^{MK} (\partial_N g_{KP} + \partial_P g_{KM} - \partial_K g_{NP}), \quad (1)$$

  $$R_{NPQ}^M = \partial_P \Gamma_{NQ}^M - \partial_Q \Gamma_{NP}^M + \Gamma_{PK}^M \Gamma_{NQ}^K - \Gamma_{QK}^M \Gamma_{NP}^K, \quad (2)$$

  $$K_{AV} = h_{A}^{C} \nabla_{CV} = \frac{1}{2} \ell_{n} h_{AB}, \quad (3)$$

  where $\ell_{n}$ denotes the Lie derivative in direction of $n_{A}$. 
CHAPTER 1

MOTIVATIONS AND INTRODUCTION

The description of the high energy physics and the interactions between elementary particles are based on gauge theories. The Standard Model and in particular QCD are examples of gauge theories. Some of the most important features of non-Abelian gauge theories and in consequence of high energy physics are not accessible through perturbation theory. Confinement and chiral symmetry breaking are examples of phenomena which need more sophisticated techniques to be explained.

During the seventies [1] G. 't Hooft realized that the perturbative series of gauge theories can be rearranged in terms of the rank of the gauge group $N_c$ and the effective coupling constant $\lambda_t = g_{YM}^2 N_c$ called 't Hooft coupling. In the limit $N_c \rightarrow \infty$ the series looks like an expansion summing over 2D surfaces, that suggested that gauge theories had an effective description in terms of a string theory model. It wasn’t until 1997 almost twenty years later that the 't Hooft ideas were realized when J. Maldacena published his very famous paper [2] which revolutionized the fields of Strings and Quantum Field Theory. This paper was the starting point of the construction of the holographic principle through the introduction of the $AdS/CFT$ correspondence which tells us that the $N=4$ $SU(N_c)$ Super-Yang-Mills (SYM) theory in 4-dimensions is dual to the type $IIB$ string theory on $AdS_5 \times S_5$. This correspondence relates the string theory coupling constant $g_s$ with $1/N_c$ and the radius of the $AdS$ space with the t’ Hooft coupling. Beside the t’ Hooft’s ideas this correspondence is also a realization of the holographic principle which says that a quantum gravity theory should be described with the degrees of freedom living at the boundary of the space. In this case the space of quantum gravity is the 10-dimensional space of the string theory and the boundary is the 4-dimensional conformal boundary associated to that space $(AdS_5 \times S_5)$. The degrees of freedom of the theory at the boundary are precisely the ones of the SYM theory. In fact, at present time $AdS/CFT$ not only refers to Maldacena’s duality but a framework of many dualities realizing the holographic principle.

The really useful fact of this duality is its weak/strong character; from the view point
of the field theory the weakly coupled situation is described by the four dimensional perturbative gauge theory but the strong coupling scenario is described by string theory in ten dimensions. An interesting application of the AdS/CFT duality is given by asymptotically AdS black holes. According to the holographic dictionary a black hole embedded in an AdS space-time is dual to a thermal state in the field theory side. One of the most important and known results of holography, at least from a phenomenological point of view is the very small lower bound in the ratio of shear viscosity to entropy density in all the Holographic plasmas which are dual to an Einstein-Hilbert gravity \( \eta/s \geq \frac{\hbar}{(4\pi\kappa_B)} \) [3]. This result had a big impact because the measure in the experiment RHIC of that ratio for the Quark-Gluon Plasma (QGP) was around \( 2.5 \times \frac{\hbar}{(4\pi\kappa_B)} \), suggesting that the plasma is in a strongly coupled regime because the prediction for \( \eta/s \) coming from weak coupling is in contrast very large.

The indications of the production of a quantum liquid in a strongly coupled regime at the experiments RHIC and more recently at the LHC, pushed forward AdS/CFT as a very promising framework to construct phenomenological models to try to understand and predict the behaviour of the QGP.

### 1.1 Kubo Formulae and Holographic Triangle Anomalies

Hydrodynamics is an ancient subject. Even in its relativistic form it appeared that everything relevant to its formulation could be found in [5]. Apart from stability issues that were addressed in the 1960s and 1970s [6,7] leading to a second order formalism there seemed little room for new discoveries. The last years witnessed however an unexpected and profound development of the formulation of relativistic hydrodynamics. The second order contributions have been put on a much more systematic basis applying effective field theory reasoning [8]. The lessons learned from applying the AdS/CFT correspondence [2] to the plasma phase of strongly coupled non-abelian gauge theories [9,10,3] played a major role (see [11] for a recent review).

The understanding of hydrodynamics is as an effective theory applicable when the mean free path of the particles is much shorter than the characteristic length scale of the system. In this regime the system can be described with the so called constitutive relations for the energy momentum tensor and the currents (the last is present if the system is charged under some global symmetry group) plus their conservation equations.

Hydrodynamics is about a system in local thermal equilibrium which means that the intensive thermodynamical parameters pressure, temperature and chemical potential (\( p, T, \mu \)) are slowly varying functions through the space-time. The last comes with the implication that constitutive relations can be written as a derivative expansion in terms of the thermody-

\[ ^1 \text{In the large } N_c \text{ limit string theory is reduced to classical gravity} \]

\[ ^2 \text{Recently has been shown that this bound can be violated if rotational symmetry is broken} \]
1.1 Kubo Formulae and Holographic Triangle Anomalies

Namical variables and the fluid velocity and the so called transport coefficients\textsuperscript{3} Very generic statements such as symmetry considerations can determine the form of the constitutive relations but cannot fix the values of the transport coefficients. To read off these coefficients it is useful to consider the theory of linear response and introduce external background fields to define the so called Kubo formulae. Having a Kubo formula allow us to compute transport coefficients in terms of retarded Green’s functions, a simple example of a Kubo formula is the one for the electric conductivity

\[ \sigma = \lim_{\omega \to 0} \frac{i}{\omega} < j^x j^x > (k = 0), \]

where \(< j^x j^x >\) is the two point retarded correlator between two electric currents. Therefore if we have a holographic description of the field theory we can use the machinery of \textit{AdS/CFT} to compute transport coefficients, because of the strong/weak nature of the duality, solving a problem of a strongly coupled field theory is reduced to a classical general relativity problem!.

During the last years a new set of transport coefficients has been discovered as a consequence of chiral anomalies. The axial anomaly of QED is responsible for two particularly interesting effects of strong magnetic fields in dense, strongly interacting matter as found in neutron stars or heavy-ion collisions. At large quark chemical potential \(\mu\), chirally restored quark matter gives rise to an axial current parallel to the magnetic field \[12,13,14\]

\[ J_5 = \frac{eN_c}{2\pi^2} \mu B, \quad (1.1) \]

which may indeed lead to observable effects in strongly magnetized neutron stars and heavy ion collisions \[15,16\], this phenomena is known as chiral separation effect (CSE).

In the context of heavy ion collisions it was argued in \[17,18\] that the excitation of topologically non-trivial gluon field configurations in the early non-equilibrium stages of a heavy ion collision might lead to an imbalance in the number of left- and right-handed quarks. This situation can be modelled by an axial chemical potential\textsuperscript{4}. During the collision one expects initial magnetic fields that momentarily exceed even those found in magnetars. It has been proposed by Kharzeev et al. \[19,20,17,18,21\] that the analogous effect \[22\]

\[ J = \frac{e^2N_c}{2\pi^2} \mu_5 B, \quad (1.2) \]

where \(J\) is the electromagnetic current and \(\mu_5\) the axial chemical potential, could render observable event-by-event P and CP violations. Indeed, there is recent experimental evidence for this chiral magnetic effect (CME) in the form of charge separation in heavy ion collisions

\textsuperscript{3}Examples of transport coefficients are electrical conductivity, shear viscosity, bulk viscosity, etc. They are intrinsic quantities associated to the system and they are determined from the microscopical theory.

\textsuperscript{4}As soon as thermal equilibrium is reached this imbalance is frozen and is modelled by a chiral chemical potential, at least as long as the electric field is zero.
Motivations and Introduction

with respect to the reaction plane [23, 24] and more recently from LHC data [25] (see however [26, 27]). For lattice studies of the effect, see for example [28, 29].

On the other hand the application of the fluid/gravity correspondence [30] to theories including chiral anomalies [31, 32] lead to another surprise: it was found that not only a magnetic field induces a current but that also a vortex in the fluid leads to an induced current, this effect is called chiral vortical effect (CVE). Again it is a consequence of the presence of chiral anomalies. It was later realized that the chiral magnetic and vortical conductivities are almost completely fixed in the hydrodynamic framework by demanding the existence of an entropy current with positive definite divergence [33]. That this criterion did not fix the anomalous transport coefficients completely was noted in [34] and various terms depending on the temperature instead of the chemical potentials were shown to be allowed as undetermined integration constants. See also [35] for a recent discussion of these anomaly coefficients with applications to heavy ion physics.

In the meanwhile Kubo formulae for the chiral magnetic conductivity [21] and the chiral vortical conductivity [36] had been developed. Up to this point only pure gauge anomalies had been considered to be relevant since the mixed gauge-gravitational anomaly in four dimensions is of higher order in derivatives and was thought not to be able to contribute to hydrodynamics at first order in derivatives. Therefore it came as a surprise that in the application of the Kubo formula for the chiral vortical conductivity to a system of free chiral fermions a purely temperature dependent contribution was found. This contribution was consistent with some of the earlier found integration constants and it was shown to arise if and only if the system of chiral fermions features a mixed gauge-gravitational anomaly [37]. In fact these contributions had been found already very early in [38]. The connection to the presence of anomalies was however not made at that time. The gravitational anomaly contribution to the chiral vortical effect was also established in a strongly coupled AdS/CFT approach and precisely the same result as at weak coupling was found [39].

The argument based on a positive definite divergence of the entropy current allows to fix the contributions from pure gauge anomalies uniquely and provides therefore a non-renormalization theorem. No such result is known thus far for the contributions of the gauge-gravitational anomaly, actually some very recent attempts to establish a non-renormalization theorems lead to the fact that the chiral vortical conductivity indeed renormalizes due to gluon fluctuations [40, 41].

A gas of weakly coupled Weyl fermions in arbitrary dimensions has been studied in [42] and confirmed that the anomalous conductivities can be obtained directly from the anomaly polynomial under substitution of the field strength with the chemical potential and the first Pontryagin density by the negative of the temperature squared [43]. Recently the anomalous conductivities have also been obtained in effective action approaches [44, 45]. The contribution of the mixed gauge-gravitational anomaly appear on all these approaches as undetermined integrations constants, but in [46] the authors argued that mixed gravitational anomaly produce a "casimir momentum" which fix the anomalous transport coefficients and explain why this anomaly been higher order in derivative contributes at lower orders.
In this thesis we will study these anomalous transport effects through the calculation of the anomalous conductivities via Kubo formulae and using the fluid/gravity correspondence. The advantage of the usage of Kubo formulae is that they capture all contributions stemming either from pure gauge or from mixed gauge-gravitational anomalies. The disadvantage is that the calculations can be performed only with a particular model and only in a weak coupled or in the gravity dual of the strong coupling regime. The fluid gravity computation allow us to confirm the independence of the anomalous transport coefficients on the intensity of the external fields because Kubo formulae are valid only in the linear response limit and also is a systematic and powerful tool to compute the influence of the anomalies into the second order transport, for which we would need three point function whether we would want to compute it using Kubo formulae.

Along the way we will explain our point of view on some subtle issues concerning the definition of currents and of chemical potentials when anomalies are present. These subtleties lead indeed to some ambiguous results [47] and [48]. A first step to clarify these issues was done in [49] and a more general exposition of the relevant issues has appeared in [50] and [51].

The thesis tries to be self-contained and is organized as follows. In chapter 2 we will briefly summarize the relevant issues concerning anomalies. We recall how vector like symmetries can always be restored by adding suitable finite counterterms to the effective action [52]. A related but different issue is the fact that currents can be defined either as consistent or as covariant currents. The hydrodynamic constitutive relations depend on what definition of current is used. We review the notion of chemical potential in the approach of the grand canonical ensemble in the chapter 3 and discuss subtleties in the definition of the chemical potential in the presence of an anomaly and define our preferred scheme. Then in chapter 4 we move to the building of relativistic hydrodynamics, constitutive relations and the derivation of the Kubo formulae that allow the calculation of the anomalous transport coefficients from two point correlators of an underlying quantum field theory.

In chapter 5 we apply the Kubo formulae to a holographic model describing a field theory system with two \( U(1) \) currents, one conserved vector current which is associated to the electromagnetic current and an anomalous one interpreted as an axial current. We also give some arguments coming from holography in favour of our preference in the introduction of anomalous chemical potentials, these arguments are also confirmed by a three point computation in field theory in the next chapter.

In Chapter 6 we apply the Kubo formulae to a theory of free Weyl fermions and show that two different contributions arise. They are clearly identifiable as being related to the presence of pure gauge and mixed gauge-gravitational anomalies.

In chapter 7 we define a holographic model that implements the mixed gauge gravitational anomaly via a mixed gauge-gravitational Chern-Simons term. We calculate the same Kubo formulae as at weak coupling, obtaining the same values for chiral axi-magnetic and chiral vortical conductivities as in the weak coupling model.

Finally in chapter 8 we apply the Fluid/Gravity correspondence to the holographic
model in order to study the second order behaviour of transport coefficients due to the gauge and mixed gauge-gravitational anomaly.

We conclude this thesis with some discussions and outlook to further developments.
Anomalies arise by integrating over chiral fermions in the path integral. They signal a fundamental incompatibility between the symmetries present in the classical theory and the quantum theory.

Unless otherwise stated we will always think of the symmetries as global symmetries. But we still will introduce gauge fields. These gauge fields serve as classical sources coupled to the currents. As a side effect their presence promotes the global symmetry to a local gauge symmetry. It is still justified to think of it as a global symmetry as long as we do not introduce a kinetic Maxwell or Yang-Mills term in the action.

In a theory with chiral fermions we define an effective action depending on these gauge fields by the path integral

\[ e^{iW_{\text{eff}}[A_\mu]/\hbar} = \int D\Psi D\bar{\Psi} e^{iS[\psi, A_\mu]/\hbar}. \]  

(2.1)

The vector field \( A_\mu(x) \) couples to a classically conserved current \( J^\mu = \bar{\Psi} \gamma^\mu Q \Psi \). The charge operator \( Q \) can be the generator of a Lie group combined with chiral projectors \( \mathcal{P}_\pm = \frac{1}{2}(1 \pm \gamma_5) \). General combinations are allowed although in the following we will mostly concentrate on a simple chiral \( U(1) \) symmetry for which we can take \( Q = \mathcal{P}_+ \). The fermions are minimally coupled to the gauge field and the classical action has an underling gauge symmetry

\[ \delta \Psi = -i\lambda(x)Q \Psi, \quad \delta A_\mu(x) = D_\mu \lambda(x), \]  

(2.2)

with \( D_\mu \) denoting the gauge covariant derivative. Assuming that the theory has a classical limit the effective action in terms of the gauge fields allows for an expansion in \( \hbar \)

\[ W_{\text{eff}} = W_0 + \hbar W_1 + \hbar^2 W_2 + \ldots \]  

(2.3)

We find it convenient to use the language of BRST symmetry by promoting the gauge pa-
rameter to a ghost field $c(x)$.

The BRST symmetry is generated by

\[ sA_\mu = D_\mu c, \quad sc = -ic^2. \]  

(2.4)

It is nilpotent $s^2 = 0$. The statement that the theory has an anomaly can now be neatly formalized. Since on gauge fields the BRST symmetry acts just as the gauge symmetry, gauge invariance translates into BRST invariance. An anomaly is present if

\[ sW_{\text{eff}} = A \quad \text{and} \quad A \neq sB. \]  

(2.5)

Because of the nil potency of the BRST operator the anomaly has to fulfill the Wess-Zumino consistency condition

\[ sA = 0. \]  

(2.6)

As indicated in (2.5) this has a possible trivial solution if there exists a local functional $B[A_\mu]$ such that $sB = A$. An anomaly is present if no such $B$ exists. The anomaly is a quantum effect. If it is of order $\hbar^n$ and if a suitable local functional $B$ exists we could simply redefine the effective action as $\tilde{W}_{\text{eff}} = W_{\text{eff}} - B$ and the new effective action would be BRST and therefore gauge invariant. The form and even the necessity to introduce a functional $B$ might depend on the particular regularization scheme chosen. As we will explain in the case of an axial and vector symmetry a suitable $B$ can be found that always allows to restore the vectorlike symmetry, this is the so-called Bardeen counterterm [52]. The necessity to introduce the Bardeen counterterm relies however on the regularization scheme chosen. In schemes that automatically preserve vectorlike symmetries, such as dimensional regularization, the vector symmetries are automatically preserved and no counterterm has to be added. Furthermore the Adler-Bardeen theorem guarantees that chiral anomalies appear only at order $\hbar$. Their presence can therefore be detected in one loop diagrams such as the triangle diagram of three currents.

We have introduced the gauge fields as sources for the currents

\[ \frac{\delta}{\delta A_\mu(x)} W_{\text{eff}}[A] = \langle \bar{\gamma}^{\mu} \rangle. \]  

(2.7)

For chiral fermions transforming under a general Lie group generated by $T^a$ the chiral anomaly takes the form [54]

\[ sW_{\text{eff}}[A] = - \int d^4 x c^a (D_\mu \partial_\mu)^a \]  

\[ = - \frac{\eta}{24\pi^2} \int d^4 x c^a \epsilon^{\mu\nu\rho\sigma} \mathrm{tr} \left[ T^a \partial_\mu \left( A_\nu \partial_\rho A_\sigma + \frac{1}{2} A_\nu A_\rho A_\sigma \right) \right]. \]  

(2.8)

Where $\eta = +1$ for left-handed fermions and $\eta = -1$ for right-handed fermions. Differentiating with respect to the ghost field (the gauge parameter) we can derive a local form. To

\footnote{A recent comprehensive review on BRST symmetry is [53].}
simplify the formulas we specialize this to the case of a single chiral $U(1)$ symmetry taking $T^a = 1$

$$\partial_\mu \delta^\mu = \frac{\eta}{96\pi^2} \epsilon^{\mu\nu\rho\sigma} F_{\mu\nu} F_{\rho\sigma}.$$  \hspace{1cm} (2.9)

This is to be understood as an operator equation. Sandwiching it between the vacuum state $|0\rangle$ and further differentiating with respect to the gauge fields we can generate the famous triangle form of the anomaly

$$\langle \partial_\mu \delta^\mu(x) \delta^\sigma(y) \delta^\kappa(z) \rangle = \frac{1}{12\pi^2} \epsilon^{\mu\sigma\rho\kappa} \partial_\mu \delta(x - y) \partial_\rho \delta(x - z).$$ \hspace{1cm} (2.10)

The one point function of the divergence of the current is non-conserved only in the background of parallel electric and magnetic fields whereas the non-conservation of the current as an operator becomes apparent in the triangle diagram even in vacuum.

By construction this form of the anomaly fulfills the Wess-Zumino consistency condition and is therefore called the consistent anomaly. In analogy we call the current defined by (2.7) the consistent current.

For a $U(1)$ symmetry the functional differentiation with respect to the gauge field and the BRST operator $s$ commute,

$$\left[ s, \frac{\delta}{\delta A_\mu(x)} \right] = 0.$$ \hspace{1cm} (2.11)

An immediate consequence is that the consistent current is not BRST invariant but rather obeys

$$s J^\mu = \frac{1}{24\pi^2} \epsilon^{\mu\nu\rho\lambda} \partial_\nu c F_{\rho\lambda} = - \frac{1}{24\pi^2} s K^\mu,$$ \hspace{1cm} (2.12)

where we introduced the Chern-Simons current $K^\mu = \epsilon^{\mu\nu\rho\lambda} A_\nu F_{\rho\lambda}$ with $\partial_\mu K^\mu = \frac{1}{2} \epsilon^{\mu\nu\rho\lambda} F_{\mu\nu} F_{\rho\lambda}$.

With the help of the Chern-Simons current it is possible to define the so-called covariant current (in the case of a $U(1)$ symmetry rather the invariant current)

$$J^\mu = \delta^\mu + \frac{1}{24\pi^2} K^\mu,$$ \hspace{1cm} (2.13)

fulfilling

$$s J^\mu = 0.$$ \hspace{1cm} (2.14)

The divergence of the covariant current defines the covariant anomaly

$$\partial_\mu J^\mu = \frac{\eta}{32\pi^2} \epsilon^{\mu\nu\rho\sigma} F_{\mu\nu} F_{\rho\sigma}.$$ \hspace{1cm} (2.15)

Notice that the Chern-Simons current cannot be obtained as the variation with respect to the gauge field of any functional. It is therefore not possible to define an effective action whose derivation with respect to the gauge field gives the covariant current.

Let us suppose now that we have one left-handed and one right-handed fermion with the corresponding left- and right-handed anomalies. Instead of the left-right basis it is more
convenient to introduce a vector-axial basis by defining the vectorlike current $J^\mu_V = J^\mu_L + J^\mu_R$ and the axial current $J^\mu_A = J^\mu_L - J^\mu_R$. Let $V_\mu(x)$ be the gauge field that couples to the vectorlike current and $A_\mu(x)$ be the gauge field coupling to the axial current. The (consistent) anomalies for the vector and axial current turn out to be

$$\partial_\mu J^\mu_V = \frac{1}{24\pi^2} \epsilon^{\mu\nu\rho\lambda} F^V_{\mu\nu} F^A_{\rho\lambda}, \quad (2.16)$$

$$\partial_\mu J^\mu_A = \frac{1}{48\pi^2} \epsilon^{\mu\nu\rho\lambda} (F^V_{\mu\nu} F^V_{\rho\lambda} + F^A_{\mu\nu} F^A_{\rho\lambda}). \quad (2.17)$$

As long as the vectorlike current corresponds to a global symmetry nothing has gone wrong so far. If we want to identify the vectorlike current with the electromagnetic current in nature we need to couple it to a dynamical photon gauge field and now the non-conservation of the vector current is worrisome to say the least. The problem arises because implicitly we presumed a regularization scheme that treats left-handed and right-handed fermions on the same footing. As pointed out first by Bardeen this flaw can be repaired by adding a finite counterterm (of order $\bar{h}$) to the effective action. This is the so-called Bardeen counterterm and has the form

$$B_{ct} = -\frac{1}{12\pi^2} \int d^4x \epsilon^{\mu\nu\rho\lambda} V_\mu A_\rho F^V_{\nu\lambda}. \quad (2.18)$$

Adding this counterterm to the effective action gives additional contributions of Chern-Simons form to the consistent vector and axial currents. With the particular coefficient chosen it turns out that the anomaly in the vector current is canceled whereas the axial current picks up an additional contribution such that after adding the Bardeen counterterm the anomalies are

$$\partial_\mu J^\mu_V = 0, \quad (2.19)$$

$$\partial_\mu J^\mu_A = \frac{1}{48\pi^2} \epsilon^{\mu\nu\rho\lambda} (3F^V_{\mu\nu} F^V_{\rho\lambda} + F^A_{\mu\nu} F^A_{\rho\lambda}). \quad (2.20)$$

This definition of currents is mandatory if we want to identify the vector current with the usual electromagnetic current in nature! It is furthermore worth to point out that both currents are now invariant under the vectorlike $U(1)$ symmetry. The currents are not invariant under axial transformation, but these are anomalous anyway.

Generalizations of the covariant anomaly and the Bardeen counterterm to the non-abelian case can be found e.g. in [54].

There is one more anomaly that will play a major role in this thesis, the mixed gauge-gravitational anomaly [55]. So far we have considered only spin one currents and have coupled them to gauge fields. Now we also want to introduce the energy-momentum tensor through its coupling to a fiducial background metric $g_{\mu\nu}$. Just as the gauge fields, the metric serves primarily as the source for insertions of the energy momentum tensor in correlation functions. Just as in the case of vector and axial currents, the mixed gauge-gravitational anomaly
anomaly is the statement that it is impossible in the quantum theory to preserve at the same
time diffeomorphisms and chiral (or axial) transformations as symmetries. It is however
possible to add Bardeen counterterms to shift the anomaly always in the sector of the spin
one currents and preserve translational (or diffeomorphism) symmetry. If we have a set
of left-handed and right-handed chiral fermions transforming under a Lie Group generated
by \((T_a)_L\) and \((T_a)_R\) in the background of arbitrary gauge fields and metric, the anomaly is
conveniently expressed through the non-conservation of the covariants current and energy
momentum tensor as

\[
D_\mu T^{\mu \nu} = F^\nu_\mu J^\mu + \frac{b_a}{384 \pi^2} \epsilon^{\rho \sigma \alpha \beta} D_\mu \left[ F_\rho \sigma R^\nu \mu \alpha \beta \right],
\]

\[
(D_\mu J^\mu)_a = \frac{d_{abc}}{32 \pi^2} \epsilon^{\mu \nu \rho \lambda} F^b_{\mu \nu} F^c_{\rho \lambda} + \frac{b_a}{768 \pi^2} \epsilon^{\mu \nu \rho \lambda} R^a_{\beta \mu \nu} R^\beta_{\alpha \rho \lambda}.
\]

The purely group theoretic factors are

\[
d_{abc} = \frac{1}{2} \text{tr}((T_a, T_b, T_c)_L) - \frac{1}{2} \text{tr}((T_a, T_b, T_c)_R),
\]

\[
b_a = \text{tr}(T_a)_L - \text{tr}(T_a)_R.
\]

Chiral anomalies are completely absent if and only if \(d_{abc} = 0\) and \(b_a = 0\).
In statistical mechanics, an equilibrium state is characterized by the grand canonical density operator \( \hat{\rho} \) which is constructed with the exponential of the conserved charges

\[
\hat{\rho} = \frac{1}{Z} e^{\beta \mu \hat{P}^\mu + \sum_a \gamma_a \hat{Q}_a}, \tag{3.1}
\]

with \( Z \) the partition function defined as \( Z = \text{Tr} e^{\beta \mu \hat{P}^\mu + \sum_a \gamma_a \hat{Q}_a} \), \( \hat{P}^\mu \) and \( \hat{Q}_a \) the momentum and charge operators. The observables’ expectation value are computed as \( \langle O \rangle = \text{Tr}[\hat{\rho} O] \). The parameters \( \beta_\mu \) and \( \gamma_a \) are Lagrange multipliers playing the role of a generalized temperature and chemical potential, \( \beta_\mu \) must be a time-like vector and can be redefined as \( \beta_\mu = -\beta u^\mu \) with the normalization condition \( u_\mu u^\mu = -1 \) and \( \gamma_a = -\beta \mu_a \). It is always possible to find a frame in which \( u^\mu = (1, 0, 0, 0) \) and the density operator recovers the usual form

\[
\hat{\rho} = \frac{1}{Z} e^{-\beta (\hat{H} + \sum_a \mu_a \hat{Q}_a)}, \tag{3.2}
\]

then we can interpret \( u^\mu \) as a velocity and then associate to the equilibrium state a velocity field, the rest frame of the system is then the one in which the operator density looks like (3.2).

In the context of quantum field theory, it is possible to find a path integral representation of the expectation value of any observable

\[
\langle \hat{O} \rangle = \int \mathcal{D}[\phi(x)] O[\phi(x)] e^{-S_E}, \tag{3.3}
\]

the integration must be done with the boundary conditions \( \phi(t - i\beta) = \pm e^{i\beta} \phi(t) \), where
Table 3.1: Two formalisms for the chemical potential

\[ \mu = \sum_a q_a \mu_a, \quad q_a \text{ the charges associated to } \phi(x) \]

\[ [\hat{Q}, \hat{\phi}^i(x)] = -q_i^j \phi^j(x) \quad (3.4) \]

and \( S_E \) the Euclidean action. The plus sign is for bosons and minus for fermions. Often in the literature the expectation value is introduced with (anti-)periodic boundary condition, to do so we have to redefine

\[ \tilde{\phi}(x) = e^{\mu t} \phi(x), \quad (3.5) \]

this redefinition has the implications that all time derivative has to be shifted by \( i\partial_0 \to i\partial_0 + \mu \) or equivalently the field theory Hamiltonian has to be deformed by

\[ H[\phi(x)] \to H[\phi(x)] - \mu Q[\phi(x)]. \quad (3.6) \]

These two formalism are completely equivalent because \( \hat{Q} \) is the generator of a real symmetry and \([\hat{H}, \hat{Q}] = 0\). In the case that concerns us \( \hat{Q} \) represent an anomalous charge, so its commutator with the Hamiltonian is not zero\(^2\) but a c-number \([\hat{H}, \hat{Q}] = c\). In this particular case defining the density operator as \((3.1)\) does not make sense because \( \hat{Q} \) is not a useful observable to label a physical state because \( \hat{Q} \neq 0 \), so in principle we do not have a first principle way to introduce the chemical potential, but still we are interested in generalize the grand partition function definition in the case of anomalous charges. To do so we will remark the physical properties of both formalism and the fact that each approach introduced before (see table: 3.1) differ by an axionic term consequence of

\[ \hat{Q} \propto A_1 \int d^3 x F \wedge F + A_2 \int d^3 x Tr[R \wedge R]. \quad (3.7) \]

One convenient point of view on formalism (B) is the following. In a real time Keldysh-Schwinger setup we demand some initial conditions at initial (real) time \( t = t_i \). These initial conditions are given by the boundary conditions in (B). From then on we do the (real) time development with the microscopic Hamiltonian \( H \). In principle there is no need for the Hamiltonian \( H \) to preserve the symmetry present at times \( t < t_i \). This seems an especially suited approach to situations where the charge in question is not conserved by the real time dynamics. In the case of an anomalous symmetry we can start at \( t = t_i \) with a state of

---

1. \( q_i^j \) is an hermitian matrix in the space of the internal degrees of freedom labelled by the indices \( i, j \).
2. If gauge fields are present.
Figure 3.1: At finite temperature field theories are defined on the Keldysh-Schwinger con-
tour in the complexified time plane. The initial state at $t_i$ is specified through the boundary
conditions on the fields. The endpoint of the contour is at $t_i - i\beta$ where $\beta = 1/T$.

certain charge. As long as we have only external gauge fields present the one-point function
of the divergence of the current vanishes and the charge is conserved. This is not true on the
full theory since even in vacuum the three-point correlators are sensitive to the anomaly. For
the formulation of hydrodynamics in external fields the condition that the one-point functions
of the currents are conserved as long as there are no parallel electric and magnetic external
fields (or a metric that has non-vanishing Pontryagin density) is sufficient.\footnote{If dynamical
gauge fields are present, such as the gluon fields in QCD even the one point function of the
charge does decay over (real) time due to non-perturbative processes (instantons) or at finite
temperature due to thermal sphaleron processes \[57\]. Even in this case in the limit of large number of colors these processes are
suppressed and can e.g. not be seen in holographic models in the supergravity approximation.}

Let us assume now that $\hat{Q}$ is an anomalous charge, i.e. its associated current suffers
from chiral anomalies. We first consider formalism (B) and ask what happens if we do
now the gauge transformation that would bring us to formalism (A). Since the symmetry is
anomalous the action transforms as

$$S[A + \partial \chi] = S[A] + \int d^4x \chi \epsilon^{\mu\nu\rho\lambda} \left( C_1 F_{\mu\nu} F_{\rho\lambda} + C_2 R^{\alpha} \beta_{\mu\nu} R^{\beta} \alpha_{\rho\lambda} \right),$$

with the anomaly coefficients $C_1$ and $C_2$ depending on the chiral fermion content. It follows
that formalisms (A) and (B) are physically inequivalent now, because of the anomaly. However,
we would like to still come as close as possible to the formalism of (A) but in a form
that is physically equivalent to the formalism (B). To achieve this we proceed by introducing
a non-dynamical axion field $\Theta(x)$ and the vertex

$$S_{\Theta}[A, \Theta] = \int d^4x \Theta \epsilon^{\mu\nu\rho\lambda} \left( C_1 F_{\mu\nu} F_{\rho\lambda} + C_2 R^{\alpha} \beta_{\mu\nu} R^{\beta} \alpha_{\rho\lambda} \right).$$

If we demand now that the “axion” transforms as $\Theta \rightarrow \Theta - \chi$ under gauge transformations
we see that the action

$$S_{\text{tot}}[A, \Theta] = S[A] + S_{\Theta}[A, \Theta]$$
is gauge invariant. Note that this does not mean that the theory is not anomalous now. We introduce it solely for the purpose to make clear how the action has to be modified such that two field configurations related by a gauge transformation are physically equivalent. It is better to consider $\Theta$ as coupling and not a field, i.e. we consider it a spurion field. The gauge field configuration that corresponds to formalism (B) is simply $A_0 = 0$. A gauge transformation with $\chi = \mu t$ on the gauge invariant action $S_{tot}$ makes clear that a physically equivalent theory is obtained by choosing the field configuration $A_0 = \mu$ and the time dependent coupling $\Theta = -\mu t$. If we define the current through the variation of the action with respect to the gauge field we get an additional contribution from $S_\Theta$,

$$J^\mu_\Theta = 4C_1 \epsilon^{\mu \nu \rho \lambda} \partial_\nu \Theta F_{\rho \lambda} ,$$  

(3.11)

and evaluating this for $\Theta = -\mu t$ we get the spatial current

$$J^m_\Theta = 8C_1 \mu B^m .$$  

(3.12)

We do not consider this to be the chiral magnetic effect! This is only the contribution to the current that comes from the new coupling that we are forced to introduce by going to formalism (A) from (B) in a (gauge)-equivalent way. As we will see in the following chapters the chiral magnetic and vortical effect are on the contrary non-trivial results of dynamical one-loop calculations.

What is the Hamiltonian now based on the modified formalism (A)? We have to take of course the new coupling generated by the non-zero $\Theta$. The Hamiltonian now is therefore

$$H - \mu \left( Q + 4C_1 \int d^3 x \epsilon^{0ijk} A_i \partial_j A_k \right) ,$$  

(3.13)

where for simplicity we have ignored the contributions from the metric terms.

For explicit computations from now on we will introduce the chemical potential through the formalism (B) by demanding twisted boundary conditions. It seems the most natural choice since the dynamics is described by the microscopic Hamiltonian $H$. The modified (A) based on the Hamiltonian (3.13) is however not without merits. Could be convenient in holography where it allows vanishing temporal gauge field on the black hole horizon and therefore a non-singular Euclidean black hole geometry.

\[4\] It is possible to define a generalized formalism to make any choice for the gauge field $A_0 = \nu$, so that one recovers formalism (A) when $\nu = \mu$ and formalism (B) when $\nu = 0$ as particular cases (see [58] for details).
4.0.1 Very brief introduction to thermodynamics

The variation of the internal energy in a thermodynamical system is

\[ dU = -pdV + TdS + \mu_a dQ_a, \]  

(4.1)

where \( p, V, S, T, \mu_a \) and \( Q_a \) are the pressure, volume, entropy, temperature, chemical potentials and conserve charges. The internal energy is an extensive function depending on the extensive variables \( V, S, Q \), so

\[ U(\lambda V, \lambda S, \lambda Q) = \lambda U(V, S, Q) \]  

(4.2)

now taking derivatives respect \( \lambda \) and evaluating at \( \lambda = 1 \) we can find that

\[ U(V, S, Q) = -pV + TS + \mu_a Q_a, \]  

(4.3)

from which we can derive

\[ Vdp = SdT + Q_a d\mu_a. \]  

(4.4)

But having in mind hydrodynamics is convenient to define the densities \( s = S/V, \epsilon = U/V \) and \( n_a = Q_a/V \) and rewrite the last expressions in term of the intensive variable

\[ \epsilon = -p + Ts + \mu_a n_a \]  

(4.5)

\[ dp = sdT + n_a d\mu_a \]  

(4.6)

\[ d\epsilon = Tds + \mu_a dn_a \]  

(4.7)

\[ ^1 \text{In this chapter we will label the number of conserved charges with the indices } a, b, \ldots \]
4.0.2 Relativistic hydrodynamics

Standard thermodynamics assumes thermodynamical equilibrium, implying that the extensive parameters \((p, T, \mu)\) are constant along the volume of the system, furthermore it is always possible to find a frame in which the total momentum of the system vanishes. In order to go to systems in a more interesting state we will allow the thermodynamical parameters to vary in space and time taking our system out of equilibrium. However we will assume local thermodynamical equilibrium which means that the variables vary slowly between the points in the volume and in time, this approximation makes sense when the mean free path of the particles is much shorter than the characteristic size or length of the system \(l_{mf} \ll L\) [59].

If we sit in a frame in which an element of fluid is at rest we will call this frame fluid rest frame. All the thermodynamical quantities defined in this frame are Lorentz invariant by construction, another important property is that local thermodynamical equilibrium implies that in this frame in such element of fluid we will have isotropy. The equations of motion are the (anomalous) conservation laws of the energy-momentum tensor and spin one currents. These are supplemented by expressions for the energy-momentum tensor and the current which are organized in a derivative expansion, the so-called constitutive relations. Symmetries constrain the possible terms. Let us construct order by order in a derivative expansion all the possible terms contributing to the energy momentum tensor and current, starting with the case with no derivatives. The presence of the fluid velocity introduce a preferred direction in space-time, so we can decompose the objects in term of their longitudinal and transverse part. To do so we define the projector

\[
P_{\mu \nu} = \delta_{\nu}^{\mu} + u^{\mu} u_{\nu}
\]

where \(u^{\mu}\) is the fluid velocity satisfying the normalization condition \(u^{\mu} u_{\mu} = -1\) and \(P_{\mu \nu}\) satisfy the properties \(P^{\mu}_{\nu} u^{\nu} = 0\), \(P^{\mu}_{\nu} P^{\nu}_{\rho} = P^{\mu}_{\rho}\) and \(P^{\mu}_{\mu} = 3\), we also define the projector on transverse traceless tensors

\[
\Pi^{\mu \nu}_{\alpha \beta} = \frac{1}{2} \left( P^{\mu}_{\alpha} P^{\nu}_{\beta} + P^{\nu}_{\alpha} P^{\mu}_{\beta} - \frac{2}{3} P^{\mu \nu} P_{\alpha \beta} \right)
\]

and the notation

\[
F^{(\mu \nu)} = \Pi^{\mu \nu}_{\alpha \beta} F^{\alpha \beta}
\]

The most general decomposition of the constitutive relations is

\[
T^{\mu \nu} = \mathcal{E} u^{\mu} u^{\nu} + \mathcal{D} P^{\mu \nu} + q^{\alpha} \left( P^{\mu}_{\alpha} u^{\nu} + P^{\nu}_{\alpha} u^{\mu} \right) + \Pi^{\mu \nu}_{\alpha \beta} \tau^{\alpha \beta}
\]

At zero order there are no gauge nor diffeomorphism covariant objects we can construct, so the only contributions allowed by symmetries are

\[
T^{\mu \nu} = \mathcal{E} u^{\mu} u^{\nu}
\]

\[
J^{\mu}_{a} = N_{a} u^{\mu}.
\]
Now we will sit in the fluid rest frame $u^\mu = (1, 0, 0, 0)$ in order to identify $\mathcal{E}$, $\mathcal{P}$ and $N_a$ with proper quantities characterizing the fluid. Then we get that the conserved quantities in matricial form look like

$$
T^{\mu \nu} = \begin{pmatrix}
-\mathcal{E} & 0 & 0 & 0 \\
0 & \mathcal{P} & 0 & 0 \\
0 & 0 & \mathcal{P} & 0 \\
0 & 0 & 0 & \mathcal{P}
\end{pmatrix}
$$

(4.15)

$$
J^{\mu}_{a} = \begin{pmatrix}
N_a \\
0 \\
0 \\
0
\end{pmatrix}
$$

(4.16)

now is easy to identify the undetermined parameters, the component $T^{00}$ is the energy density, $T^{ii}$ the pressure and $J^0_a$ the charge density in the local rest frame, so we conclude that the constitutive relations at zero order in the derivative expansion are the one for an ideal fluid

$$
T^{\mu \nu}_{(0)} = \mathcal{E}u^{\mu}u^{\nu} + \mathcal{P}u^{\mu}u^{\nu}
$$

(4.17)

$$
J^{\mu}_{(0)a} = n_a u^{\mu}.
$$

(4.18)

The knowledge of the constitutive relations\footnote{Including the so-called transport coefficients} and the (non) conservation laws is enough to describe the full dynamic of the fluid. In a system with diffeomorphism invariance in 3 + 1 dimensions the most general conservation equations we can have are

$$
D_{\mu}T^{\mu \nu} = F^{\mu \nu} J_{a} - 2\lambda_a D_{\nu} + \left[ \mathcal{E}^{\rho \sigma \alpha \beta} F_{\alpha \beta} R^{\mu \nu} \right],
$$

(4.19)

$$
(D_{\mu}J_{a})^{\mu} = \mathcal{E}^{\mu \nu \rho \lambda} \left( 3\kappa_{abc} F_{\mu \nu} F_{\rho \lambda} + \lambda_a R^{\mu \nu \alpha \beta} \right),
$$

(4.20)

where we have redefined $\kappa_{abc} = \frac{d_{abc}}{96\pi^2}$ and $\lambda_a = \frac{b_a}{768\pi^2}$.

Now using these equation together with the zero order constitutive relations (4.17), (4.18) and (4.5), (4.7) it is straightforward to prove that for such a fluid there exists a conserved current which mimics how the local entropy varies along the fluid and that there is no entropy production per particle species

$$
D_{\mu}(su^{\mu}) = 0, \quad u^{\mu} D_{\mu} \left( sn_a^{-1} \right) = 0,
$$

(4.21)

so we define the zero order entropy current as

$$
S^{\mu} = su^{\mu}.
$$

(4.22)
Notice that we have been able to construct the constitutive relations and the second law of thermodynamics using symmetry arguments and the equation of motions. The procedure at higher order in the derivatives will have the same spirit.

Before going to the higher order analysis let us remark that out of equilibrium the fluid velocity and the thermodynamical variables are not well defined quantities, the basic reason is the non existence of quantum operators to which we can associate their expectation value to such observables. So we can define many local temperatures $T(x)$ that differ from each other by gradients of hydro variables but coincide in their equilibrium value when the gradients vanish. This implies that the coefficients $E, N$ and $P$ have to be of the form

$$E = \varepsilon(T, \mu) + f_E(\partial T, \partial \mu, \partial u), \quad (4.23)$$
$$P = p(T, \mu) + f_P(\partial T, \partial \mu, \partial u), \quad (4.24)$$
$$N = n(T, \mu) + f_N(\partial T, \partial \mu, \partial u), \quad (4.25)$$

with $f_E, f_P$ and $f_N$ determined by the particular definition of the fields $T(x), \mu(x)$ and $u^\mu(x)$. The choice of those fields is often called to select a frame. On the other hand the energy momentum tensor and charged current are physical quantities, so they cannot depend on the ambiguity of choosing a frame. Considering a redefinition of the type

$$T(x) \rightarrow T(x) + \delta T(x) \quad (4.26)$$
$$\mu(x) \rightarrow \mu(x) + \delta \mu(x) \quad (4.27)$$
$$u^\mu(x) \rightarrow u^\mu(x) + \delta u^\mu(x), \quad (4.28)$$

demanding invariance of $T^{\mu\nu}$ and $J^\mu$ under such transformations and the normalization condition it is possible to realize that for an arbitrary redefinition of hydro variables this relations have to be always satisfied

$$\delta E = 0, \quad \delta P = 0, \quad \delta N = 0, \quad (4.29)$$
$$\delta q_\mu = - (E + P) \delta u_\mu, \quad \delta j_\mu = - N \delta u_\mu, \quad (4.30)$$
$$\delta \tau_{\mu\nu} = 0. \quad (4.31)$$

The tensor part of the system is frame independent consequence of these transformations but the vector and scalar parts are not. However these transformations allow us to define a frame independent vector and scalar

$$j^\mu_a = j^\mu_a - \frac{n_a}{\varepsilon + p} q^\mu, \quad (4.32)$$
$$f = f_\mu - \left( \frac{\partial p}{\partial \varepsilon} \right)_n f_\varepsilon - \left( \frac{\partial p}{\partial n} \right)_\varepsilon f_N. \quad (4.33)$$

In this particular case the entropy current is conserved because we are working with the ideal constitutive relations in what follows when we consider dissipative process we will demand $D_\mu S^\mu \geq 0$

The same happen for the rest of the variables
Without loss of generality it is always possible to fix \( f_E = f_N = 0 \). This gauge only allows higher order corrections to the local pressure but maintain the functions \( E \) and \( N \) been the energy density and charge density respectively.

Now it is time to build up the first order constitutive relations, to do so it is useful to decompose the derivatives of the velocity in term of transverse and longitudinal objects.

\[
D^\nu u^\mu = -a^\mu u^\nu + \sigma ^{\mu \nu} + \frac{1}{2} \omega ^{\mu \nu} + \frac{1}{3} \theta P^{\mu \nu} \tag{4.34}
\]

where \( a^\mu \) (acceleration), \( \sigma ^{\mu \nu} \) (shear tensor), \( \omega ^{\mu \nu} \) (vorticity tensor) and \( \theta \) (expansion) are defined as

\[
\theta = D_\mu u^\mu = P^{\mu \nu} D_\mu u_\nu \tag{4.35}
\]
\[
a^\mu = u^\nu D_\nu u^\mu \equiv D u^\mu \tag{4.36}
\]
\[
\sigma ^{\mu \nu} = D(\mu u^\nu) + u(\mu a^\nu) - \frac{1}{3} \theta P^{\mu \nu} = D^{(\mu u^\nu)} \tag{4.37}
\]
\[
\omega ^{\mu \nu} = 2D^{\mu}u^\nu + 2u^{\mu}a^\nu = 2P^{\mu \alpha}P^{\nu \beta}D^{\alpha \beta}, \tag{4.38}
\]

notice that it is also possible to define a vorticity pseudo vector

\[
\omega ^\mu = \frac{1}{2} \varepsilon ^{\mu \nu \rho \lambda} u_\nu \omega _{\rho \lambda}. \tag{4.39}
\]

It is straightforward to notice that the vorticity and shear tensors are transverse and traceless and the acceleration is longitudinal. Now using the background fields \( A^a_\mu \) and \( g_{\mu \nu} \) the only objects we can construct with only one derivative are the electric and magnetic field

\[
F^{a \mu \nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + g f^{a b c} A^b_\mu A^c_\nu \tag{4.40}
\]
\[
E^a_\mu = F^{a \mu \nu} u^\nu \tag{4.41}
\]
\[
B^{\mu a} = \frac{1}{2} \varepsilon ^{\mu \nu \rho \lambda} u_\nu F^{a \rho \lambda}, \tag{4.42}
\]

finally we have to build up one derivative quantities with thermodynamical parameters, in particular we will chose the combinations \( \bar{\mu} = \mu / T \) and \( T \) as the independent variables. Besides we can observe that using the ideal energy and charge conservation we get that there is only one independent scalar and five independent vectors, so we choose the scalar \( \theta \) and the independent vectors

\[
P^{\mu \nu} D_\nu \bar{\mu}, \quad P^{\mu \nu} D_\nu T, \quad \omega ^\mu, \quad E^a_\mu \quad \text{and} \quad B^{\mu a}. \tag{4.43}
\]

Now we will study the \( (C, P) \) properties of each object \(^5\) in order to classify the transport coefficients in terms of the anomalous and non anomalous one. Under \( C \) and \( P \) the

\(^5\)Notice that there are no diffeomorphism covariant quantities constructed with the metric and containing only one derivative.

Figure 4.1: $C, P$ properties of the first order scalars, vectors and tensors

The metric tensor is even and the epsilon tensor even and odd respectively. The vectors $u^\mu$, $D_\mu$, $J_\mu$, $S^\mu$, and $A_\mu$ under parity behave like vectors so they are odd, the gauge field and current are also odd under charge conjugation but the velocity, derivative and entropy current are even. From the constitutive relations $J_\mu = a_n u^\mu + \ldots$, $S^\mu = su^\mu + \ldots$ we conclude that $a_n$ has $(C, P) = (-, -)$ and $s$ $(+, +)$ in consequence $\mu_n$ and $T$ transform in the same way to its conjugated variables. Having this in mind we can do the following analysis, all the transport coefficients have to be a function $f(\bar{\mu}, \kappa, \lambda)$, each of these functions will have a definite $(C, P)$ depending on the combinations $(\bar{\mu}, \kappa, \lambda, \kappa \bar{\mu}, \lambda \bar{\mu})$, so the possible combinations are

$$(+,-) : f(\bar{\mu}, \kappa, \lambda) = g(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) \quad (4.44)$$

$$(-,-) : f(\bar{\mu}, \kappa, \lambda) = \bar{\mu} g(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) + \lambda g_2(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) \quad (4.45)$$

$$(-,+) : f(\bar{\mu}, \kappa, \lambda) = \kappa \bar{g}_1(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) + \lambda \bar{g}_2(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) \quad (4.46)$$

$$(+,+) : f(\bar{\mu}, \kappa, \lambda) = \bar{\mu} \kappa \bar{g}_1(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) + \bar{\mu} \lambda \bar{g}_2(\bar{\mu}^2, \kappa^2, \lambda^2, \kappa \lambda) \quad (4.47)$$

With this classification we can select systematically all the transport coefficients which are present if and only if the system presents anomalies. The part of the constitutive relations associated to the transport coefficients with $(C, P) = (+, -)$ will be split respect the ordinary part. Finally that we have classified all the contributions we can write the first order corrections to the constitutive relations as,

$$f_\nu = -\zeta \theta, \quad (4.48)$$

$$\tilde{f}_\nu = 0, \quad (4.49)$$

$$\tau^{\mu\nu} = -2\eta \sigma^{\mu\nu}, \quad (4.50)$$

$$\tilde{\tau}^{\mu\nu} = 0, \quad (4.51)$$

$$q^\alpha_a = \bar{\xi}_a E_\alpha^\mu + \xi_0^2 p^{\alpha\nu} D_\nu \bar{\mu}_a + \xi_0^3 p^{\alpha\nu} D_\nu T, \quad (4.52)$$

$$\tilde{q}^\alpha_a = \sigma_a^{(e, B)} B_a^\mu + \sigma_a^{(e, V)} \omega^\mu, \quad (4.53)$$

$$\tilde{j}^a_\alpha = \bar{\Omega}_{ab} E^\mu_b + \Omega_{ab}^{\alpha\nu} D_\nu \bar{\mu}_b + \Omega_3 p^{\alpha\nu} D_\nu T, \quad (4.54)$$

$$\tilde{j}^a_\alpha = \sigma_{ab} B^\mu_b + \sigma_a^{e, V} \omega^\mu, \quad (4.55)$$

We use tildes to distinguish the anomalous terms from the rest.

$^6 f(\bar{\mu}, \kappa, \lambda)$ is also a function of the temperature but because of its trivial behaviour under $C$ and $P$ it will be ignored in this analysis. We are also ignoring the index structure of the quantities.
And in a frame invariant language

\begin{align}
 l_a^\mu &= -\Sigma_{ab} E_b^\mu - \bar{\Sigma}_{ab} P^{\alpha \nu} D_{\nu} \bar{\mu}_b + \xi_{ab} \beta_{ab}^\mu + \bar{\xi}_{ab} \alpha_{ab}^\nu \omega^\mu + \chi_{a}^T P^{\alpha \nu} D_{\nu} T, \\
 f &= -\zeta \theta, 
\end{align}

with

\begin{align}
 \Sigma_{ab} &= \left( \Omega_{ab}^1 - \frac{n_a}{\varepsilon + p} \xi_1 \right), \\
 \bar{\Sigma}_{ab} &= \left( \Omega_{ab}^2 - \frac{n_a}{\varepsilon + p} \bar{\xi}_b \right), \\
 \xi_{ab}^B &= \left( \sigma_{ab}^B - \frac{n_a}{\varepsilon + p} \sigma_{ab}^{(e,B)} \right), \\
 \bar{\xi}_{ab}^V &= \left( \sigma_{a}^{V} - \frac{n_a}{\varepsilon + p} \sigma_{a}^{(e,V)} \right), \\
 \chi_{a}^T &= \left( \Omega_{a}^3 - \frac{n_a}{\varepsilon + p} \xi^3 \right).
\end{align}

It is possible to constrain it more using the second law of thermodynamics \((D_\mu S^\mu \geq 0)\). Combining the (non) conservation equations up to second order corrections is possible to find a modification of the equation (4.21)

\begin{align}
 D_\mu S^\mu &= -\bar{\mu}_a \mu_a^\mu \mu_a - \left( \frac{E_\mu}{T} - D_\mu \beta_a \right) J_\mu^{(1)} - D_\mu \left( \frac{\eta_\alpha}{T} T^{\alpha \beta} \right) J^{(1)}_{\beta} + D_\mu s^\mu_{(1)}, 
\end{align}

with \(S^\mu\) defined as

\begin{align}
 S^\mu &= s u^\mu - \bar{\mu}_a \mu_a^\mu - \frac{\eta_\alpha}{T} T^{\alpha \beta} + \zeta^\mu, \\
 \zeta^\mu &= \chi_{a} B_{a}^\mu + \bar{\chi} \omega^\mu.
\end{align}

This current satisfy the property \(u_\mu S^\mu = -s\) which is the covariant expression to the statement that in the rest frame the zero component of \(S^\mu\) is the entropy density \(s\). Substituting in (4.61) the equations (4.50) - (4.55) we can find a set of restrictions the transport coefficients must obey in order to always have a positive divergence of the entropy current. The most commons frames used are the so called Landau frame and Eckart frame. The Landau frame is defined requiring that in the rest frame of an element of fluid the energy flux to vanish, this condition is realized in covariant form as

\begin{align}
 u_{\mu} T_{\mu \gamma} = 0. 
\end{align}

On the other hand the Eckart frame demand the presence of some conserved charge in the fluid and define the velocity field as the velocity of those charges, so \(J_{\mu}^{(n)} = 0\).

After imposing the positivity of \(D_\mu S^\mu\) we get the most general form for the constitutive relations for the energy-momentum tensor and the currents in the Landau frame are

\begin{align}
 T^{\mu \nu} &= \varepsilon u^\mu u^\nu + (p - \zeta \theta) P^{\mu \nu} - 2\eta \sigma^{\mu \nu}, \\
 J_{\mu} &= n_a u^\mu + \Sigma_{ab} \left( E_{b}^\mu - T P^{\mu \alpha} D_{\alpha} \bar{\mu}_b \right) + \xi_{ab} B_{ab}^\mu + \bar{\xi}_{ab} \omega^\mu, \\
 \eta_n > 0
\end{align}
with the dissipative transport coefficients satisfying the conditions \( \eta \geq 0, \ \zeta \geq 0, \ \Sigma_{ab} \geq 0, \ \bar{\Sigma}_{ab} = T \Sigma_{ab}, \ \chi_a^T = 0 \) and the anomalous one [33][34]

\[
\xi_{ab}^B = 24 \bar{\kappa}_{abc} \mu_c - \frac{n_a}{\varepsilon + p} \left( 12 \bar{\kappa}_{abc} \mu_c \mu_d + \beta_b T^2 \right) \tag{4.66}
\]

\[
\xi_a^V = 12 \bar{\kappa}_{abc} \mu_b \mu_c + \beta_a T^2 - \frac{n_a}{\varepsilon + p} \left( 8 \bar{\kappa}_{bcd} \mu_b \mu_c \mu_d + 2 \beta_b \mu_b T^2 + \gamma T^3 \right) \tag{4.67}
\]

\[
\chi_a = \frac{12}{T} \bar{\kappa}_{abc} \mu_b \mu_c + \beta_a T \tag{4.68}
\]

\[
\bar{\chi} = \frac{4}{T} \bar{\kappa}_{abc} \mu_b \mu_c + \beta_a \mu_a T + \gamma T^2, \tag{4.69}
\]

where \( \beta_a \) and \( \gamma \) are free numerical integration constants, notice that \( \gamma \neq 0 \) breaks CPT [34], so a non vanishing value for that constant is allowed only for non preserving parity theories. A different story comes with the value of the constant \( \beta_a \) which is completely unconstrained by this method. It is important to specify that these are the constitutive relations for the covariant currents!

### 4.0.3 Linear response and Kubo formulae

To compute the Kubo formulae for the anomalous transport coefficients it turns out that the Landau frame is not the most convenient one. It fixes the definition of the fluid velocity through energy transport. Transport phenomena related to the generation of an energy current are therefore not directly visible, rather they are absorbed in the definition of the fluid velocity. It is therefore more convenient to go to another frame in which we demand that the definition of the fluid velocity is not influenced when switching on an external magnetic field or having a vortex in the fluid. In such a frame the constitutive relations for the system take the form

\[
T^{\mu \nu} = \varepsilon u^\mu u^\nu + (p - \zeta \theta) P^{\mu \nu} - \eta \sigma^{\mu \nu} + \tilde{q}^\mu u^\nu + \tilde{q}^\nu u^\mu \tag{4.70}
\]

\[
\tilde{q}^\mu = \sigma_a^{(e,B)} B_a^\mu + \sigma_a^{(e,V)} \omega^\mu \tag{4.71}
\]

\[
J_a^\mu = n_a u^\mu + \Sigma_{ab} \left( E_b^\mu - T P^{\mu \alpha} D_\alpha \left( \frac{H_b}{T} \right) \right) + \sigma_{ab} B_b^\mu + \sigma_a^V \omega^\mu. \tag{4.72}
\]

In order to avoid unnecessary clutter in the equations we have specialized now to a single \( U(1) \) charge. Notice that now there is a sort of “heat” current present in the constitutive relation for the energy-momentum tensor.

The derivation of Kubo formulae is better based on the usage of the consistent currents. Since the covariant and consistent currents are related by adding suitable Chern-Simons currents the constitutive relations for the consistent current receives additional contribution from

---

8 We will see below that \( \beta_a \) is not arbitrary but is completely fixed by the mixed gauge gravitational anomaly coefficient \( \lambda_a \).
the Chern-Simons current
\[ \mathcal{J}^\mu = J^\mu - \frac{1}{24\pi^2} K^\mu. \]  (4.73)

If we were to introduce the chemical potential according to formalism A (table: 3.1) via a deformation of the field theory Hamiltonian we would get an additional contribution to the consistent current from the Chern-Simons current. In this case it is better to go to the modified formalism \(A'\) that also introduces a spurious axion field and another contribution to the current \(J_\theta\) (3.12) has to be added
\[ \mathcal{J}^\mu = J^\mu - \frac{1}{24\pi^2} K^\mu + J_\theta^\mu. \]  (4.74)

For the derivation of the Kubo formulae it is therefore more convenient to work with formalism \((B)\) in which the chemical potential is introduced via the boundary condition shown in table: 3.1. Otherwise there arise additional contributions to the two point functions. We will briefly discuss them in the next chapter.

From the microscopic view the constitutive relations should be interpreted as the one-point functions of the operators \(T^{\mu\nu}\) and \(\mathcal{J}^\mu\) in a near equilibrium situation, i.e. gradients in the fluid velocity, the temperature or the chemical potentials are assumed to be small. From this point of view Kubo formulae can be derived. In the microscopic theory the one-point function of an operator near equilibrium is given by linear response theory whose basic ingredient are the retarded two-point functions. If we consider a situation with the space-time slightly deviating from Minkowski \(g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}\) in such a way that the only non vanishing deviation is \(h_{xy} = h_{xy}(t)\) and all other sources switched off, i.e. the fluid being at rest \(u^\mu = (1,0,0,0)\) and no gradients in temperature, chemical potentials or gauge fields the energy momentum tensor is simplified to
\[ T^{xy} \equiv \langle T^{xy} \rangle = -p h_{xy} - \eta \dot{h}_{xy}. \]  (4.75)

Fourier transforming the equation \(\dot{h}_{xy} = i\omega h_{xy}\) and using linear response theory the energy momentum tensor is given through the retarded two-point function by
\[ T^{xy} = \langle T^{xy} T^{xy} \rangle h_{xy}. \]  (4.76)

Equating the two expressions for the expectation value of the energy momentum tensor we find the Kubo formula for the shear viscosity
\[ \eta = \lim_{\omega \to 0} -\frac{1}{\omega} \text{Im} \langle \langle T^{xy} T^{xy} \rangle \rangle. \]  (4.77)

This has to be evaluated at zero momentum. The limit in the frequency follows because the constitutive relation are supposed to be valid only to lowest order in the derivative expansion, therefore one needs to isolate the first non-trivial term.

Now we want to find some simple special cases that allow the derivation of Kubo formulae for the anomalous conductivities. A very convenient choice is to go to the rest
frame \( u^\mu = (1, 0, 0, 0) \), switch on a vector potential in the \( y \)-direction that depends only on the \( z \) direction and at the same time a metric deformation \( ds^2 = -dt^2 + h_{ty} dt dy + dx^2 \) with \( h_{ty} = A_y^g(z) \). It is clear that such a gauge field introduce a background magnetic field pointing in the \( x \) direction \( B^x = -\partial_z A_y^g \), analogously happens with the metric. In linearised gravity is well known that a perturbation like the introduced above behave as an abelian gauge field (see [61]), the gravito-magnetic field will be \( B^g_x = -\partial_z A_y^g \). To linear order in the background fields the non-vanishing components of the energy-momentum tensor and the current are

\[
T^{0x} = \sigma_B^p B_x + \sigma_V^p B_x^g, \\
J^x = \sigma_B B_x + \sigma_V B_x^g.
\]

Notice that in the place of the vorticity field the gravito-magnetic field appear, that happens because in the rest frame the lower index velocity looks like \( u_\mu = (-1, 0, A_y^g, 0) \), in consequence the vorticity coincide with the gravito-magnetic field, so at linear order the chiral vortical effect can be understood as a chiral gravito-magnetic effect.\(^9\)

Now going to momentum space and differentiating with respect to the sources \( A_y \) and \( h_{0y} \) we find therefore the Kubo formulae [18, 36]

\[
\begin{align*}
\sigma_B = \lim_{k_z \to 0} i k_z \langle J^0 J^y \rangle, \\
\sigma_V = \lim_{k_z \to 0} i k_z \langle J^x T^{0y} \rangle, \\
\sigma_B^\epsilon = \lim_{k_z \to 0} i k_z \langle T^{0x} J^y \rangle, \\
\sigma_V^\epsilon = \lim_{k_z \to 0} i k_z \langle T^{0x} T^{0y} \rangle.
\end{align*}
\]

All these correlators are to be taken at precisely zero frequency. As these formulas are based on linear response theory the correlators should be understood as retarded ones. They have to be evaluated however at zero frequency and therefore the order of the operators can be reversed. From this it follows that the chiral vortical conductivity coincides with the chiral magnetic conductivity for the energy flux \( \sigma_V = \sigma_B^\epsilon \). These formulas are part of the key point of this thesis because we will use them to compute those transport coefficients in weakly and strongly coupled regimes.

We also want to discuss how these transport coefficients are related to the ones in the more commonly used Landau frame. They are connected by a redefinition of the fluid velocity of the form

\[
u^\mu \to u^\mu - \frac{1}{\varepsilon + p} q^\mu,
\]

\(^9\)see [62]
to directly identify the transport coefficients in such a frame.

\[
\xi_B = \lim_{k_n \to 0} \frac{-i}{2k_n} \sum_{k,l} \epsilon_{nkl} \left( \langle \delta^k \delta^l \rangle - \frac{n}{\epsilon + p} \langle T^0_k T^0_l \rangle \right),
\]

(4.82)

\[
\xi_V = \lim_{k_n \to 0} \frac{-i}{2k_n} \sum_{k,l} \epsilon_{nkl} \left( \langle \delta^k T^0_l \rangle - \frac{n}{\epsilon + p} \langle T^0_k T^0_l \rangle \right),
\]

(4.83)

where we have employed a slightly more covariant notation. The generalization to the non-
abelian case is straightforward.

It is also worth to compare to the Kubo formulae for the dissipative transport coeffi-
cients [4.77]. In the dissipative cases one first goes to zero momentum and then takes the
zero frequency limit. In the anomalous conductivities this is the other way around, one first
goes to zero frequency and then takes the zero momentum limit. Another observation is that
the dissipative transport coefficients sit in the anti-Hermitean part of the retarded correlators,
i.e. the spectral function whereas the anomalous conductivities sit in the Hermitean part. The
rate at which an external source \( f_i \) does work on a system is given in terms of the spectral
function of the operator \( O^I \) coupling to that source as

\[
\frac{dW}{dt} = \frac{1}{2} \omega f_i (-\omega) \rho^I (\omega) f_j (\omega).
\]

(4.84)

The anomalous transport phenomena therefore do no work on the system, first they take place
at zero frequency and second they are not contained in the spectral function \( \rho = \frac{i}{2} (G_r - G_r^\dagger) \).

### 4.0.4 Second Order expansion

Now we want to go a step forward in the derivative expansion and to make our work easier
and having applications to holography in mind, from now on we will consider the case of
conformal fluids. This assumption introduces a big simplification in order to build up the
second order constitutive relations because of the big symmetry restriction introduced with
the conformal symmetry.

Some notion on conformal/Weyl covariant formalism is needed to construct the con-
stitutive relations up to second order, for a detailed explanation see [63]. A conformal fluid
has to be invariant under the change

\[
g_{\mu\nu} \rightarrow e^{-2\phi(x)} g_{\mu\nu},
\]

(4.85)

where \( \phi(x) \) is an arbitrary function. We will say that a tensor is Weyl covariant with weight
\( w \) if transform as

\[
T^{\alpha\beta...}_{\mu\nu...} \rightarrow e^{w\phi(x)} T^{\alpha\beta...}_{\mu\nu...}.
\]

(4.86)

The consequences of conformal symmetry on hydrodynamics are, that the energy
momentum tensor and (non)-conserved currents have to be covariant under Weyl transfor-
mations and the energy momentum has to be traceless modulo contributions from Weyl
Relativistic Hydrodynamics with Anomalies

Table 4.1: Weyl weights for the chemical potential, temperature, fluid velocity, metric, pressure, charge density, electric field and magnetic field.

anomaly. To construct Weyl covariant quantities it is necessary to introduce the Weyl connection

$$\mathcal{A}_\mu = u^\nu D_\mu u_\nu - \frac{1}{3} D_\nu u^\nu \quad (4.87)$$

and a Weyl covariant derivative

$$D_\lambda Q^\mu_{\ldots} = D_\lambda Q^\mu_{\ldots} - w A_\lambda Q^\mu_{\ldots} +$$

$$+ [g_{\lambda\alpha} A^\mu - \delta^\mu_\lambda A_\alpha - \delta^\alpha_\lambda A^\mu] Q^\alpha_{\ldots} + \ldots$$

$$- [g_{\lambda\nu} A^\alpha - \delta^\alpha_\lambda A^\nu - \delta^\nu_\lambda A^\alpha] Q^\mu_{\ldots} + \ldots \quad (4.88)$$

It is possible to reduce in a systematic way the number of independent sources contributing to the constitutive relations imposing Weyl covariance and the hydrodynamical equation of motions (Ward identities). In the Refs. [60, 31, 32] a classification in the so called Landau frame of all the possible term that can appear in the energy momentum tensor and U(1) current has been done up to second order. The Ward identities in four dimensions in presence of quantum anomalies are shown in (4.20) and (4.19), the curvature part was always neglected because is fourth order in derivative and the expansion was done up to second order. But in [37, 39] was shown that the gravitational anomaly indeed fixed part of the transport coefficient at first order, actually in [46] was understood why the derivative expansion breaks down in presence of the gravitational anomaly.

Before start writing the constitutive relations it is useful to study the Weyl weight of the hydro variables (see table: 4.1).

Now with these ingredients we can write down the constitutive relations split in the equilibrium, first and second order part in the Landau Frame

$$T^{\mu\nu} = p (4 u^\mu u^\nu + \eta^{\mu\nu}) + \tau_{(1)}^{\mu\nu} + \tau_{(2)}^{\mu\nu} + \tau_{(3)}^{\mu\nu} \quad (4.89)$$

$$j^{\mu} = n u^{\mu} + j_{(1)}^{\mu} + j_{(2)}^{\mu} + j_{(3)}^{\mu} \quad (4.90)$$

the subindex in parenthesis means the order in derivative. Weyl invariance implies the equation of state $\varepsilon = 3p$ and the vanishing of the bulk viscosity $\zeta = 0$. Remembering the contri-
butons at first order in a Weyl covariant language

$$\tau^{\mu\nu}_{(1)} = -2\eta \sigma^{\mu\nu}$$  \hspace{1cm} (4.91)

$$j_{\mu}^{(1)} = \xi_\nu \omega^{\mu} + \xi_\beta B^{\mu} , \quad j_{(1)}^{\mu} = -\Sigma \left( TP^{\mu\nu} D_\nu \mu - E^{\mu} \right),$$  \hspace{1cm} (4.92)

with the shear and vorticity tensors rewritten as

$$\sigma_{\mu\nu} = \frac{1}{2}(D_\mu u_\nu + D_\nu u_\mu)$$  \hspace{1cm} (4.93)

$$\omega_{\mu\nu} = D_\mu u_\nu - D_\nu u_\mu.$$  \hspace{1cm} (4.94)

The second order sources can be constructed using the same method as in the first order with the extra consideration of being Weyl covariant see [60], beside the derivative of the first order objects we have a new covariant object which is the conformal Weyl tensor of the background metric $C_{\mu\nu\rho\lambda}$. So, the full set of second order corrections are

$$\tau^{\mu\nu}_{(2)} = \sum_{a=1}^{a=15} \lambda_a (a^{\mu\nu}), \quad \tilde{\tau}^{\mu\nu}_{(2)} = \sum_{a=1}^{a=8} \lambda_a (a^{\mu\nu}),$$  \hspace{1cm} (4.95)

$$j_{\mu}^{(2)} = \sum_{a=1}^{a=10} \xi_\nu (a^{\mu}), \quad j_{(2)}^{\mu} = \sum_{a=1}^{a=5} \xi_\nu (a^{\mu}).$$

with the second order vector and tensors defined as

$$\mathcal{T}^{(1)\mu\nu} = u^\alpha D_\alpha \sigma^{\mu\nu} \quad \mathcal{T}^{(2)\mu\nu} = \sigma^{(\mu\gamma} \sigma^{\nu)} \gamma \quad \mathcal{T}^{(3)} = \sigma^{(\mu\omega^{\mu})\gamma}$$

$$\mathcal{T}^{(4)\mu\nu} = \omega^{(\mu\gamma} \omega^{\nu)} \gamma \quad \mathcal{T}^{(5)\mu\nu} = D^{(\mu} D^{\nu)} \mu \quad \mathcal{T}^{(6)\mu\nu} = D^{(\mu} \mu D^{\nu)} \mu$$

$$\mathcal{T}^{(7)\mu\nu} = D^{(\mu} E^{\nu)} \quad \mathcal{T}^{(8)\mu\nu} = E^{(\mu} D^{\nu)} \quad \mathcal{T}^{(9)\mu\nu} = E^{(\mu} E^{\nu)}$$

$$\mathcal{J}^{(10)\mu\nu} = B^{(\mu} B^{\nu)} \quad \mathcal{J}^{(11)\mu\nu} = J^{(\gamma} \eta^{\mu} u_\gamma B^{\nu)} \quad \mathcal{J}^{(12)\mu\nu} = \omega^{(\mu} B^{\nu)}$$

$$\mathcal{J}^{(13)\mu\nu} = C^{\mu\nu} \quad \mathcal{J}^{(14)\mu\nu} = \epsilon^{(\mu\alpha\beta} \epsilon^{\nu\delta\eta} C^{\alpha\beta\delta\eta} u_\gamma u_\lambda \quad \mathcal{J}^{(15)\mu\nu} = \epsilon^{(\mu\gamma\delta\eta} C^{\nu\delta\eta} u_\gamma u_\lambda$$  \hspace{1cm} (4.96)

$$\tilde{\mathcal{T}}^{(1)\mu\nu} = D^{(\mu} \omega^{\nu)} \quad \tilde{\mathcal{T}}^{(2)\mu\nu} = \omega^{(\mu} D^{\nu)} \mu \quad \tilde{\mathcal{T}}^{(3)} = \epsilon^{\delta\eta (\mu} \sigma^{\nu)} \eta u_\gamma D_\delta \mu$$

$$\tilde{\mathcal{T}}^{(4)\mu\nu} = D^{(\mu} B^{\nu)} \quad \tilde{\mathcal{T}}^{(5)\mu\nu} = B^{(\mu} D^{\nu)} \mu \quad \tilde{\mathcal{T}}^{(6)\mu\nu} = E^{(\mu} B^{\nu)}$$

$$\tilde{\mathcal{T}}^{(7)\mu\nu} = \epsilon^{\gamma\delta (\mu} \sigma^{\nu)} u_\gamma E_\delta \quad \tilde{\mathcal{T}}^{(8)\mu\nu} = \omega^{(\mu} E^{\nu)}$$  \hspace{1cm} (4.97)

$$\tilde{\mathcal{J}}^{(1)\mu} = \sigma^{\mu\nu} D_\nu \tilde{\mu} \quad \tilde{\mathcal{J}}^{(2)\mu} = \omega^{\mu\nu} D_\nu \tilde{\mu} \quad \tilde{\mathcal{J}}^{(3)\mu} = \rho^{\mu\nu} D_\alpha \sigma^{\nu\alpha}$$

$$\tilde{\mathcal{J}}^{(4)\mu} = \rho^{\mu\nu} D_\alpha \omega^{\nu\alpha} \quad \tilde{\mathcal{J}}^{(5)\mu} = \sigma^{\mu\nu} E_\nu \quad \tilde{\mathcal{J}}^{(6)\mu} = \omega^{\mu\nu} E_\nu$$

$$\tilde{\mathcal{J}}^{(7)\mu} = u^\nu D_\nu E_\mu \quad \tilde{\mathcal{J}}^{(8)\mu} = \epsilon^{\nu\alpha\beta} u_\nu B_\alpha D_\beta \tilde{\mu} \quad \tilde{\mathcal{J}}^{(9)\mu} = \epsilon^{\nu\alpha\beta} u_\nu E_\alpha B_\beta$$  \hspace{1cm} (4.98)

$$\tilde{\mathcal{J}}^{(10)\mu} = \epsilon^{\mu\nu\alpha} u_\nu D_\alpha B_\beta \quad \tilde{\mathcal{J}}^{(11)\mu} = \sigma^{\mu\nu} \omega^{\nu} \quad \tilde{\mathcal{J}}^{(12)\mu} = \sigma^{\mu\nu} B_\nu \quad \tilde{\mathcal{J}}^{(13)\mu} = \omega^{\mu\nu} B_\nu$$  \hspace{1cm} (4.99)
In chapter: [8] we will compute all these second order transport coefficients using a holographic model which realize both gravitational and gauge anomalies, but we shall assume the fluid living in a flat space time, so the contribution to constitutive relations coming from the curvature tensor will be ignored.
The anomalous conductivities (1.1) and (1.2) have been studied in holographic models of QCD by introducing chemical potentials for left and right chiral quarks as boundary values for corresponding bulk gauge fields [64, 47]. However, it was pointed out by Ref. [48] that in these calculations the axial anomaly was not realized in consistent form and that the corresponding electromagnetic current was not strictly conserved. Correcting the situation by means of Bardeen’s counterterm [52, 65] instead led to a vanishing result for the electromagnetic current in the holographic QCD model due to Sakai and Sugimoto [66, 67] while recovering the result (1.1) for the anomalous axial conductivity. Indeed, the two anomalous conductivities (1.1) and (1.2) differ in that in the former case there is no difficulty with introducing a chemical potential for quark number, while a chemical potential for chirality refers to a chiral current that is anomalous. In [49] we solved the problem of introducing chemical potential for anomalous charges, realizing (holographically) the differences between the formalism resumed in table [3.1] in the case of anomalous charges.

5.0.5 Comparing formalisms and Kubo formulae computation

Now we want to give a detailed analysis of the different Feynman graphs that contribute to the Kubo formulae in the different formalisms for the chemical potentials. The simplest and most economic formalism is certainly the one labeled (B) in which we introduce the chemical potentials via twisted boundary conditions. The Hamiltonian is simply the microscopic Hamiltonian $H$. Relevant contributions arise only at first order in the momentum and at zero frequency and in this kinematic limit only the Kubo formulae for the chiral magnetic conductivity is affected. In the figure (5.1) we summarize the different contributions to the Kubo

---

1In Ref. [68] a finite result was obtained in a bottom-up model that is nonzero only due to extra scalar fields.
The first of the Feynman graphs is the same in all formalisms. It is the genuine finite temperature and finite density one-loop contribution. This graph is finite because the Fermi-Dirac distributions cutoff the UV momentum modes in the loop. In the formalism (A) we need to take into account that there is also a contribution from the triangle graph with the fermions going around the loop in vacuum. For a non-anomalous symmetry this graph vanishes simply because on the upper vertex of the triangle sits a field configuration that is a pure gauge. If the symmetry under consideration is however anomalous the triangle diagram picks up just the anomaly. Even pure gauge field configurations become physically distinct from the vacuum and therefore this diagram gives a non-trivial contribution. On the level of the constitutive relations this contribution corresponds to the Chern-Simons current in (4.73). We consider this contribution to be unwanted. After all the anomaly would make even a constant value of the temporal gauge field $A_0$ observable in vacuum. An example is provided for a putative axial gauge field $A_5^\mu$. If present the absolute value of its temporal component would be observable through the axial anomaly. We can be sure that in nature no such background field is present. The third line $(A')$ introduces also the spurious axion field $\Theta$ the only purpose of this field is to cancel the contribution from the triangle graph. This cancellation takes place by construction since $(A')$ is gauge equivalent to $(B)$ in which only the first genuine finite $T, \mu$ part contributes. It corresponds to the contribution of the current $J_\Theta^\mu$ in (4.74). We further emphasize that these considerations are based on the usage of the consistent currents.

In the interplay between axial and vector currents additional contributions arise from the Bardeen counterterm. It turns out that the triangle or Chern-Simons current contribution

---

2This Feynman diagram analysis only makes sense in a weak coupled theory, but anyway gives us an useful understanding of the physics.
to the consistent vector current in the formalism \((A)\) cancels precisely the first one \([48, 49]\) as we shall see below. Our take on this is that a constant temporal component of the axial gauge field \(A_0^5 = \mu_5\) would be observable in nature and can therefore be assumed to be absent. The correct way of evaluating the Kubo formulae for the chiral magnetic effect is therefore the formalism \((B)\) or the gauge equivalent one \((A')\).

At this point the reader might wonder why we introduced yet another formalism \((A')\) which achieves apparently nothing but being equivalent to formalism \((B)\). At least from the perspective of holography there is a good reason for doing so. In holography the strong coupling duals of gauge theories at finite temperature in the plasma phase are represented by five dimensional asymptotically Anti- de Sitter black holes. Finite charge density translates to charged black holes. These black holes have some non-trivial gauge flux along the holographic direction represented by a temporal gauge field configuration of the form \(A_0^0(r)\) where \(r\) is the fifth, holographic dimension. It is often claimed that for consistency reasons the gauge field has to vanish on the horizon of the black hole and that its value on the boundary can be identified with the chemical potential

\[
A_0(r_H) = 0 \quad \text{and} \quad A_0(r \to \infty) = \mu,
\]

is important to remark that the l.h.s. of \((5.1)\) is just a gauge fixation and the boundary condition is the r.h.s.

According to the usual holographic dictionary the gauge field values on the boundary correspond to the sources for currents. A non-vanishing value of the temporal component of the gauge field at the boundary is therefore dual to a coupling that modifies the Hamiltonian of the theory just as in \((3.6)\). Thus with the boundary conditions \((5.1)\) we have the holographic dual of the formalism \((A)\). If anomalies are present they are represented in the holographic dual by five-dimensional Chern-Simons terms of the form \(A^\wedge F^\wedge F\). The two point correlator of the (consistent) currents receives now contributions from the Chern-Simons term that is precisely of the form of the second graph in \((A)\) in figure 5.1. As we have argued this is an a priory unwanted contribution. We can however cure that by introducing an additional term in the action of the form \((3.9)\) living only on the boundary of the holographic space-time. In this way we can implement the formalism \((A')\), cancel the unwanted triangle contribution with the third graph in \((A')\) in figure 5.1 and maintain \(A_0(r_H) = 0\)!

The claim that the temporal component of the gauge field has to vanish at the horizon is of course not unsubstantiated. The reasoning goes as follows. The Euclidean section of the black-hole space time has the topology of a disc in the \(r, \tau\) directions, where \(\tau\) is the Euclidean time. This is a periodic variable with period \(\beta = 1/T\) where \(T\) is the (Hawking) temperature of the black hole and at the same time the temperature in the dual field theory. Using Stoke’s law we have

\[
\int_{\partial D} A_0 d\tau = \int_D F_{\phi0} dr d\tau,
\]

where \(F_{\phi0}\) is the electric field strength in the holographic direction and \(D\) is a Disc with origin at \(r = r_H\) reaching out to some finite value of \(r_f\). If we shrink this disc to zero size, i.e. let
Figure 5.2: A sketch of the Euclidean black hole topology. A singularity at the horizon arises if we do not choose the temporal component of the gauge field to vanish there. On the other hand allowing the singularity to be present changes the topology to the one of a cylinder and this in turn allows twisted boundary conditions.

$r_f \to r_H$ the r.h.s. of the last equation vanishes and so must the l.h.s. which approaches the value $\beta A_0(r_H)$. This implies that $A_0(r_H) = 0$. If on the other hand we assume that $A_0(r_H) \neq 0$ then the field strength must have a delta type singularity there in order to satisfy Stokes theorem. Strictly speaking the topology of the Euclidean section of the black hole is not anymore that of a disc since now there is a puncture at the horizon. It is therefore more appropriate to think of this as having the topology of a cylinder. Now if we want to implement the formalism $(B)$ in holography we would find the boundary conditions

$$A_0(r_H) = \mu \quad (5.3)$$

and the gauge fixation $A_0(r \to \infty) = 0$ and precisely such a singularity at the horizon would arise. In addition we would need to impose twisted boundary conditions around the Euclidean time $\tau$ for the fields just as in (table: 3.1). Now the presence of the singularity seems to be a good thing: if the space time would still be smooth at the horizon it would be impossible to demand these twisted boundary conditions since the circle in $\tau$ shrinks to zero size there. If this is however a singular point of the geometry we can not really shrink the circle to zero size. The topology being rather a cylinder than a disc allows now for the presence of the twisted boundary conditions.

It is also important to note that in all formalisms the potential difference between the boundary and the horizon is given by $\mu$. This has a very nice intuitive interpretation. If we bring a unit test charge from the boundary to the horizon we need the energy $\Delta E = \mu$. In the dual field theory this is just the energy cost of adding one unit of charge to the thermalized system and coincides with the elementary definition of the chemical potential. In this chapter we will consider the “boundary condition”

$$A_0(r_H) - A_0(r \to \infty) = \mu \quad (5.4)$$

with non gauge fixation for that component of the gauge field in order to illustrate the above discussion.
5.1 The (holographic) Model

It is important to distinguish between thermodynamic state variables such as chemical potentials and background gauge fields (as also pointed out by Ref. [69]). Recall that the holographic dictionary instructs us to construct a functional of boundary fields and that n-point functions are obtained by functional differentiation with respect to the boundary fields. For a gauge field the expansion close to the boundary takes the form

\[ A_\mu(x, r) = A_\mu^{(0)}(x) + \frac{A_\mu^{(2)}(x)}{r^2} + \ldots. \]

The leading term in this expansion is the source for the current \( J^\mu \). The subleading term is often identified with the one-point function of the current. This is, however, not true in general. As has been pointed out in Ref. [48], in the presence of a bulk Chern-Simons term, the current receives also contributions from the Chern-Simons term and \( A_\mu^{(2)}(x) \) can, in general, not be identified with the vev of the current. On the other hand a constant value of \( A_0^{(0)} \) is often identified with a chemical potential. This is, however, slightly misleading since the holographic realization of the chemical potential is given by the potential difference between the boundary and the horizon and only in a gauge in which the \( A_0 \) vanishes at the horizon such an identification can be made. Even in this case we have to keep in mind that the boundary value of the gauge field is the source of the current whereas the potential difference between horizon and boundary is the chemical potential.

5.1 The (holographic) Model

We will consider the simplest possible holographic model for one quark flavor in a chirally restored deconfined phase.\(^3\) It consists of taking two gauge fields corresponding to the two chiralities for each quark flavor in a five dimensional AdS black hole background.

The action is given by two Maxwell actions for left and right gauge fields plus separate Chern Simons terms corresponding to separate anomalies for left and right chiral quarks. The Chern-Simons terms are however not unique but can be modified by adding total derivatives. A total derivative which enforces invariance under vector gauge transformations \( \delta V_M = \partial_M \lambda(V) \) corresponds to the so-called Bardeen counterterm [52, 65], leading to the action

\[ S = \int d^5x \sqrt{-g} \left( -\frac{1}{4g_V^2} F^{(V)}_{MN} F^{(V)}_{MN} - \frac{1}{4g_A^2} F^{(A)}_{MN} F^{(A)}_{MN} + \frac{\kappa}{2} \epsilon^{MNPQR} A_M F^{(A)}_{NP} F^{(A)}_{QR} + 3 F^{(V)}_{NP} F^{(V)}_{QR} \right) \] (5.5)

Since the Chern-Simons term depends explicitly on the gauge potential \( A_M \) the action is gauge invariant under \( \delta A_M = \partial_M \lambda(A) \) only up to a boundary term. This non-invariance is the holographic implementation of the axial \( U(1) \) anomaly, when identifying the gauge fields as holographic sources for the currents of global \( U(1) \) symmetries in the dual field theory. A

\(^3\)The even simpler model considered in Ref. [69] is instead closer to a single quark flavor in a chirally broken phase where right and left chiralities are living on the two boundaries of a single brane.
rigorous string-theoretical realization of such a setup is provided for example by the Sakai-Sugimoto model \[66, 67\]. As usually done in the latter, we neglect the backreaction of the bulk gauge fields on the black hole geometry.

In order to compute the field equations and the boundary action, from which we shall obtain the two- and three-point functions of various currents, we expand around fixed background gauge fields and to second order in fluctuations. The gauge fields are written as

\[
A_M = A_M^{(0)} + a_M, \quad V_M = V_M^{(0)} + v_M
\]

where the \(A_M^{(0)}\) and \(V_M^{(0)}\) are the background fields and the lower case letters are the fluctuations.

After a little algebra we find to first order in the fluctuations

\[
\delta S_{\text{bulk+}\partial}^{(1)} = \int_{\text{bulk}} dr d^4x \sqrt{-g} \left\{ a_M \left[ \frac{1}{g_A^2} \nabla_N \mathcal{F}^{NM} + \frac{3\kappa}{2} \epsilon^{MNPQR} (\mathcal{F}^{(A)}_{NP} \mathcal{F}^{(A)}_{QR} + \mathcal{F}^{(V)}_{NP} \mathcal{F}^{(V)}_{QR}) \right] + v_M \left[ \frac{1}{g_V^2} \nabla_N \mathcal{F}^{NM}_{(V)} + 3\kappa \epsilon^{MNPQR} (\mathcal{F}^{(A)}_{NP} \mathcal{F}^{(V)}_{QR}) \right] \right\} + \int_{\partial} d^4x \left[ a_\mu \left( \frac{1}{g_A^2} \sqrt{-g} \mathcal{F}^{\mu r}_{(A)} + 2\kappa \epsilon^{\mu\nu\rho\lambda} A_{\nu} \mathcal{F}^{(A)}_{\rho\lambda} \right) \right. \\
\left. + v_\mu \left( \frac{1}{g_V^2} \sqrt{-g} \mathcal{F}^{\mu r}_{(V)} + 6\kappa \epsilon^{\mu\nu\rho\lambda} A_{\nu} \mathcal{F}^{(V)}_{\rho\lambda} \right) \right],
\]

where calligraphic strength tensors refer to the background ones. From the bulk term we get the equations of motion and from the boundary terms we can read the expressions for the non renormalized consistent currents,

\[
\mathcal{J}^\mu = \left[ \frac{1}{g_V^2} \sqrt{-g} \mathcal{F}^{\mu r}_{(V)} + 6\kappa \epsilon^{\mu\nu\rho\lambda} A_{\nu} \mathcal{F}^{(V)}_{\rho\lambda} \right] \right\}
\]

On-shell they obey

\[
\partial_\mu \mathcal{J}^\mu = 0,
\]

As expected, the vector like current is exactly conserved. Comparing with the standard result from the one loop triangle calculation we find \(\kappa = -\frac{N_c}{24\pi^2}\) for a dual strongly coupled SU(\(N_c\)) gauge theory for a massless Dirac fermion in the fundamental representation.

We emphasize that only by demanding an exact conservation law for the vector current we can consistently couple it to an (external) electromagnetic field. This leaves no ambiguity
in the definitions of the above currents as the ones obtained by varying the action with respect to the gauge fields and which obey (5.10). In particular, we have to keep the contributions from the Chern-Simons terms in the action, which are occasionally ignored in holographic calculations.

The second order term in the expansion of the action is

$$S^{(2)}_{\text{bulk}+\partial} = \int_{\text{bulk}} \left\{ \frac{1}{2g_A^2} \nabla f^{NM}_N + \frac{3}{2} \epsilon^{MNPQR} (f^{(A)P}_N f^{(A)Q}_R + f^{(V)P}_N f^{(V)Q}_R) \right\} +$$

$$\int_{\partial} \left\{ \frac{1}{2g_V^2} \nabla f^{NM}_V + \frac{3}{2} \epsilon^{MNPQR} (f^{(A)P}_N f^{(A)Q}_R + f^{(V)P}_N f^{(V)Q}_R) \right\} +$$

$$\int_{\partial} \left[ \frac{\sqrt{-g}}{2} \left( \frac{1}{g_A^2} a_\mu f^{\mu r}_N + \frac{1}{g_V^2} v_\mu f^{\mu r}_V + \kappa \epsilon^{\mu\nu\rho\lambda} (A_\nu a_\mu f^{(A)\rho\lambda}_N + 3v_\mu A_\nu f^{(V)\rho\lambda}_N + 3v_\mu a_\nu f^{(V)\rho\lambda}_V) \right) \right] ,$$

where $f_{MN}$ is the field strength of the fluctuations. Again the action is already in the form of bulk equations of motion plus boundary term.

As gravitational background we take the planar AdS Schwarzschild metric

$$ds^2 = -f(r) dt^2 + \frac{dr^2}{f(r)} + r^2 (dx^2 + dy^2 + dz^2) .$$

with $f = \frac{r^2}{L^2} - \frac{r^4}{L^2}$. The temperature is given in terms of the horizon by $r_+ = L^2 \pi T$. We rescale the $r$ coordinate such that the horizon lies at $r = 1$ and we also will set the AdS scale $L = 1$. Furthermore we also rescale time and space coordinates accordingly. To recover the physical values of frequency and momentum we thus have to do replace $(\omega, k) \rightarrow (\omega/(\pi T), k/(\pi T))$.

The background gauge fields are

$$A_0^{(0)}(r) = \Phi(r) = \alpha - \frac{\beta}{r^2} ,$$

$$V_0^{(0)}(r) = \Psi(r) = \nu - \frac{\gamma}{r^2} .$$

As we said before we will introduce the chemical potential as the difference of energy in the system with a unit of charge at the boundary and a unit of charge at the horizon. the integration constants $\beta$ and $\gamma$ are thus fixed to

$$\beta = \mu_5 \quad (5.15)$$

$$\gamma = \mu \quad (5.16)$$

where $\mu$ is the chemical potential of the vector symmetry and $\mu_5$ the chemical potential of the axial $U(1)$. The constants $\alpha$ and $\nu$ we take to be arbitrary and we will eventually consider them as sources for insertions of the operators $j^0_0$ and $j^5_0$ at zero momentum. Due to our choice of coordinates the physical value of the chemical potentials is recovered by $\mu \rightarrow \pi T \mu$. 

We can now compute the charges present in the system from the zero components of the currents \( (5.8) \)

\[
J^0 = \frac{2\gamma}{g_V} \quad (5.17)
\]

\[
J^0_5 = \frac{2\beta r}{g_A^2} \quad (5.18)
\]

It is important to realize that without a Chern-Simons term the action for a gauge field in the bulk depends only on the field strengths and is therefore independent of constant boundary values of the gauge field. The action does, of course, depend on the physically measurable difference of the potential between the horizon and the boundary. For our particular model, the choice of the Chern-Simons term results, however, also in an explicit dependence on the integration constant \( \alpha \). It is crucial to keep in mind that \( \alpha \) is a priori unrelated to the chiral chemical potential but plays the role of the source for the operator \( J^0_5 \) at zero momentum.

For the fluctuations we choose the gauge \( a_r = 0 \). We take the fluctuations to be of plane wave form with frequency \( \omega \) and momentum \( k \) in \( x \)-direction. The relevant polarizations are then the \( y \)- and \( z \)-components, i.e. the transverse gauge field fluctuations. The equations of motion are

\[
v_{a}'' + \left( \frac{f}{r} + \frac{1}{r} \right)v_{a}' + \frac{(\omega^2 r^2 - f k^2)}{f^2 r^2} v_{a} + \frac{12i\kappa g_V^2 k}{fr} \epsilon_{ab} (\Phi'v_{b} + \Psi'_{a} a_{b}) = 0, \quad (5.19)
\]

\[
a_{a}'' + \left( \frac{f}{r} + \frac{1}{r} \right)a_{a}' + \frac{(\omega^2 r^2 - f k^2)}{f^2 r^2} a_{a} + \frac{12i\kappa g_V^2 k}{fr} \epsilon_{ab} (\Phi'a_{b} + \Psi'v_{b}) = 0. \quad (5.20)
\]

Prime denotes differentiation with respect to the radial coordinate \( r \). The two-dimensional epsilon symbol is \( \epsilon_{yz} = 1 \).

There is also a longitudinal sector of gauge field equations. They receive no contribution from the Chern-Simons term and so are uninteresting for our purposes.

The boundary action in Fourier space in the relevant transversal sector is

\[
S^{(2)} = \int d\theta \left[ -\frac{rf}{2} \frac{1}{g_A^2} d^b_{-k}(d^b_{k})' + \frac{1}{g_A^2} v_{-k}^{b}(v_{k}^{b})' - 2i k \kappa \epsilon_{bc} \alpha \left( d^b_{-k} a_{k}^{c} + 3 v_{-k}^{b} v_{k}^{c} \right) \right] \quad (5.21)
\]

As anticipated, the second order boundary action depends on the boundary value of the axial gauge field but not on the boundary value of the vector gauge field.

From this we can compute the holographic Green function. The way to do this is to compute four linearly independent solutions that fulfill infalling boundary conditions on the horizon \([72] [73]\). At the AdS boundary we require that the first solution asymptotes to the vector \( (v_y, v_z, a_y, a_z) = (1, 0, 0, 0) \), the second solution to the vector \( (0, 1, 0, 0) \) and so on. We can therefore build up a matrix of solution \( F_{b}^{T} J(r) \) where each column corresponds to one of these solutions \([74]\). Given a set of boundary fields \( a_{i}^{(0)}(k), v_{i}^{(0)}(k) \) which we collectively
5.1 The (holographic) Model

arrange in the vector \( \phi^I(k) \), the bulk solution corresponding to these boundary fields is

\[
\phi^I(k, r) = F^I_{k J} \phi^J(k) \tag{5.22}
\]

\( F \) is the (matrix valued) bulk-to-boundary propagator for the system of coupled differential equations.

The holographic Green function is then given by

\[
G_{IJ} = -\lim_{r \to \infty} (A_{IL}(F^L_{k J})' + B_{IJ}) \tag{5.23}
\]

The matrices \( A \) and \( B \) can be read off from the boundary action as

\[
A = -\frac{1}{2} r f \begin{pmatrix} 1 & 0 \\ g^2(r) & 1 \end{pmatrix}, \quad B = -2i\kappa k \alpha \begin{pmatrix} 3\epsilon_{ij} & 0 \\ 0 & \epsilon_{ij} \end{pmatrix} \tag{5.24}
\]

(notice that \( F \) becomes the unit matrix at the boundary).

We are interested here only in the zero frequency limit and to first order in an expansion in the momentum \( k^0 \). In this limit the differential equations can be solved explicitly. To this order the matrix bulk-to-boundary propagator is

\[
F = \begin{pmatrix}
1 & -g^2 \mu s g(r) & 0 & -g^2 \mu g(r) \\
0 & 1 & g^2 \mu g(r) & 0 \\
g^2 \mu s g(r) & 0 & 1 & -g^2 \mu s g(r) \\
g^2 \mu g(r) & 0 & g^2 \mu s g(r) & 1
\end{pmatrix} \tag{5.25}
\]

where \( g(r) = 6i\kappa \log(1 + 1/r^2) \). We find then the holographic current two-point functions in presence of the background boundary gauge fields \( A_0 = \nu \) and \( A_5^0 = \alpha \)

\[
\langle J^a_{5} J^b_{5} \rangle = -4i\kappa k (3\mu_5 - \alpha) \epsilon_{ab} \tag{5.28}
\]

Although \( \mu, \mu_5 \) and the boundary gauge field value \( \alpha \) enter in very similar ways in this result, we need to remember their completely different physical meaning. The chemical potentials \( \mu \) and \( \mu_5 \) are gauge invariant physical state variables whereas \( \alpha \) is the source for insertions of \( J_5^a(0) \). Had we chosen the “gauge” \( \alpha = \mu_5 \) we would have concluded (erroneously) that the two-point correlator of electric currents vanishes. We see now that with \( \mu_5 \) introduced separately from \( \alpha \) that this not so. We simply have obtained expressions for the correlators in the physical state described by \( \mu \) and \( \mu_5 \) in the external background fields \( \alpha \) and \( \nu \). Due to the gauge invariance of the action under vector gauge transformations the constant mode of the source \( \nu \) does not appear. The physical difference between the chemical potentials and

\footnote{In this approximation the on shell action does not need to be renormalized}
the gauge field values is clear now. The susceptibilities of the two-point functions obtained by differentiating with respect to the chemical potentials are different from the three-point functions obtained by differentiating with respect to the gauge field values. Finally, we remark that the temperature dependence drops out due to the opposite scaling of \( k \) and \( \mu, \mu_5 \).

To compute the anomalous conductivities we therefore have to evaluate the two-point function for vanishing background fields \( \nu = \alpha = 0 \). We obtain, in complete agreement with the well-known weak coupling results,

\[
\sigma_{\text{CME}} = \lim_{k \to 0} \frac{ie_{ab}}{2k} \langle j^a_5 j^b_5 \rangle |_{\nu = \alpha = 0} = \frac{N_c}{2\pi^2} \mu_5, \\
\sigma_{\text{CSE}} = \lim_{k \to 0} \frac{ie_{ab}}{2k} \langle j^a_5 j^b_5 \rangle |_{\nu = \alpha = 0} = \frac{N_c}{2\pi} \mu, \\
\sigma_{55} = \lim_{k \to 0} \frac{ie_{ab}}{2k} \langle j^a_5 j^b_5 \rangle |_{\nu = \alpha = 0} = \frac{N_c}{2\pi^2} \mu_5.
\]

We are tempted to call all \( \sigma \)'s conductivities. This is, however, a slight misuse of language in the case of \( \sigma_{55} \). Formally \( \sigma_{55} \) measures the response due to the presence of an axial magnetic field \( \vec{B}_5 = \nabla \times \vec{A}_5 \). Since such fields do not exist in nature, we cannot measure \( \sigma_{55} \) in the same way as \( \sigma_{\text{CME}} \) and \( \sigma_{\text{CSE}} \).

Since the two-point functions (5.26) still depend on the external source \( \alpha \) we can also obtain the three point functions in a particular kinematic regime. Differentiating with respect to \( \alpha \) (and \( \nu \)) we find the three point functions

\[
\langle j^a(k) j^b(-k) j^0(0) \rangle = 0, \\
\langle j^a_5(k) j^b_5(-k) j^0_5(0) \rangle = 0, \\
\langle j^a_5(k) j^b_5(-k) j^0_5(0) \rangle = 0, \\
\langle j^a(k) j^b(-k) j^0_5(0) \rangle = -ik \frac{N_c}{2\pi^2} \epsilon_{ab}, \\
\langle j^a_5(k) j^b_5(-k) j^0_5(0) \rangle = 0, \\
\langle j^a_5(k) j^b_5(-k) j^0_5(0) \rangle = -ik \frac{1}{3} \frac{N_c}{2\pi^2} \epsilon_{ab}.
\]

Note the independence on chemical potentials and temperature. Therefore, these expression hold also in vacuum.

Although the anomaly is conventionally expressed through the divergence of the axial current we can also see it from these three-point functions containing the axial current at zero momentum. The zero component of the current at zero momentum is nothing but the total charge \( Q \) and \( Q_5 \). Since all currents are neutral they should commute with the charges and if we are not in a situation of spontaneous symmetry breaking the vacuum should be annihilated by the charge. From this it follows that insertions of \( Q \) into correlation functions of currents should annihilate them. And this is indeed what an insertion of the electric
charge \( Q \) does. Insertion of \( Q \) however does result in a non trivial three-point correlator and therefore expresses the non-conservation of axial charge!

Equations (5.35) and (5.37) show the sensitivity of the theory to a constant temporal component of the axial gauge field even at zero temperature and chemical potentials. If the axial \( U(1) \) symmetry was exactly conserved, such a constant field value would be a gauge degree of freedom and the theory would be insensitive to it. Since this symmetry is, however, anomalous, it couples to currents through these three-point functions. The correlators (5.35) and (5.37) can therefore be understood as expressing the anomaly in the axial \( U(1) \) symmetry.

In the next chapter we will check these results in vacuum at weak coupling by calculating the triangle diagram in the relevant kinematic regimes, this consistency check will come as a confirmation that our intuition comparing formalism (table 3.1) is the right one and that we have to compute expectation values at finite temperature with anomalous charges either in formalism (B) or formalism (A').
An important property of the two- and three-point functions we just calculated is that they are independent of temperature. The three-point functions are furthermore independent of the chemical potentials. Therefore, the results for the three-point function should coincide with correlation functions in vacuum. So in this chapter we will start computing the three point functions (5.32)-(5.37) in vacuum and then we will move to a finite temperature and chemical potential situation to compute two point functions and use the Kubo formulae (4.80) to extract the anomalous transport coefficients.

### 6.1 Three point functions at weak coupling

At weak coupling all the three-point functions can be obtained from a single 1-loop Feynman integral. We only need to evaluate the diagram with two vector currents and one axial current. The diagram with three vector currents vanishes identically (due to C-parity) and the one with three axial currents can be reduced to the one with only one axial current by anticommuting $\gamma_5$ matrices (when a regularization is applied that permits this). Similarly, it can be seen that the diagram with two axial vector currents can be reduced to the one with none, which vanishes.

When computing the three-point function, it is crucial to check the resulting anomalies. Gauge invariant regulators, like dimensional regularization, should yield the correct anomaly, such that the vector currents are identically conserved. On the other hand, for example cutoff regularization breaks gauge invariance and further finite renormalizations may be needed in order to restore gauge invariance. In the following, we apply both dimensional and cutoff regularizations to compute the three-point function and show that they give consistent results with each other and with Eqs. (5.32)-(5.37).
6.1.1 Triangle diagram with one axial current

The triangle diagram, shown in Fig. 6.1, with one axial current and two vector currents is given by

\[ \Gamma^{\mu \nu \rho}(p, q) = (-1)(ie)^2(ig)(i)^3 \int \frac{d^d l}{(2\pi)^d} \text{tr} \left( \gamma_5 \frac{l - p}{(l - p)^2} \gamma_\mu \gamma^\nu \frac{l + q}{(l + q)^2} \gamma^\rho \right) \]

\[ + (\mu \leftrightarrow \nu, p \leftrightarrow q). \quad (6.1) \]

The factors are a \((-1)\) from the fermion loop, the couplings to vector and axial gauge fields and \(i\) for each fermion propagator. We will simply set the electric and axial couplings \(e\) and \(g\) to one. Evaluation of the integral with dimensional and cutoff regularizations is presented in some detail in Appendix A.

The anomalies of the various currents coupled to the triangle diagram are obtained by contracting the three-point function above by the corresponding momenta. Applying dimensional regularization, we get immediately

\[ p_\mu \Gamma^{\mu \nu \rho}_{\text{DR}}(p, q) = 0, \quad (6.2) \]

\[ q_\nu \Gamma^{\mu \nu \rho}_{\text{DR}}(p, q) = 0, \quad (6.3) \]

\[ (p + q)_\rho \Gamma^{\mu \nu \rho}_{\text{DR}}(p, q) = \frac{i}{2\pi^2} p_\alpha q_\beta \epsilon^{\alpha \beta \mu \nu}, \quad (6.4) \]

yielding the correct Adler-Bell-Jackiw anomaly. In terms of cutoff regularization, we how-
ever find

\[ p_\mu \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = -\frac{i}{6\pi^2} p_\alpha q_\beta \epsilon^{\alpha \beta \nu \rho}, \quad (6.5) \]

\[ q_\nu \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = \frac{i}{6\pi^2} p_\alpha q_\beta \epsilon^{\alpha \beta \mu \rho}, \quad (6.6) \]

\[ (p + q)_\rho \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = \frac{i}{6\pi^2} p_\alpha q_\beta \epsilon^{\alpha \beta \mu \nu}. \quad (6.7) \]

In order to cancel the anomalies in the vector current, we must perform an additional finite renormalization by adding the Bardeen counterterm,

\[ \Gamma^{\text{ct}} = c \int d^4x \epsilon^{\mu \nu \rho \lambda} V_\mu A_5^\nu F_{\rho \lambda}, \quad (6.8) \]

where \( F_{\rho \lambda} = \partial_\rho V_\lambda - \partial_\lambda V_\rho \). This vertex brings an additional contribution to the three-point function, and the full result reads

\[ \Gamma^{\mu \nu \rho} = \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) + 2ic(p_\lambda - q_\lambda) \epsilon^{\lambda \mu \nu \rho}. \quad (6.9) \]

Choosing the coefficient \( c \) of the Bardeen counterterm appropriately, \( c = \frac{1}{12\pi^2} \), we find the anomaly equations

\[ p_\mu \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = 0, \quad (6.10) \]

\[ q_\nu \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = 0, \quad (6.11) \]

\[ (p + q)_\rho \Gamma^{\mu \nu \rho}_{\text{CO}}(p, q) = \frac{i}{2\pi^2} p_\alpha q_\beta \epsilon^{\alpha \beta \mu \nu}. \quad (6.12) \]

in full agreement with the the result from dimensional regularization and the conservation of the vector current.

We next want to evaluate the triangle diagram in the special kinematic regimes of Eqs. (5.32)-(5.37). Taking \( q = -p \), corresponding to the three-point function in Eq. (5.35), only the integrands \( A \) and \( B \) in Eqs. (A.12)-(A.23) contribute and take the values \( 1/2 \) and \(-1/2 \) in dimensional regularization and \( 1/6 \) and \(-1/6 \) in cutoff, respectively. The three-point function is then

\[ \Gamma^{\mu \nu \rho}(p, -p) = \frac{i}{2\pi^2} \epsilon^{\alpha \mu \nu \rho} p_\alpha, \quad (6.13) \]

in agreement with Eq. (5.35). Note that with cutoff regularization, \( \frac{1}{3} \) of this result comes from the loop diagram and \( \frac{2}{3} \) comes from the counterterm.

Let us next take \( p = 0 \), \( i.e. \) we put zero momentum on one of the vector currents. The corresponding loop integral vanishes in dimensional regularization, while the loop contribution in cutoff regularization is precisely cancelled by the contribution from the counterterm,

\[ \Gamma^{0 \nu \rho}(0, -q) = 0. \quad (6.14) \]

This result is in agreement with Eq. (5.33)
6.1.2 Triangle diagram with three axial currents

From the same one loop integral we can also compute the correlator of three axial currents\footnote{\textsuperscript{1}}. Since we can anticommute the $\gamma_5$ and use $\gamma_5^2 = -1$, we can reduce this diagram to (6.1). The Bardeen counterterm, however, does not contribute this time, and we therefore find

$$\Gamma_{\mu \nu 0} = \frac{1}{3} \frac{i}{2\pi} e^{\alpha \mu \nu 0} p_\alpha ,$$

just as in Eq. (5.37). The factor $\frac{1}{3}$ is fixed by demanding Bose symmetry on the external legs.

All other current three-point functions can be related to the triangle with three vector currents which is known to vanish. Therefore we have indeed reproduced the holographic results in Eqs. (5.32)-(5.37)\footnote{\textsuperscript{2} Notice that we are using in this chapter the capital letters $A,B,C\ldots$ to label the number of conserved currents.}, which is a non trivial check that we have introduced in a right way the anomalous chemical potential.

6.2 Thermal two point functions

In the present section we will use the Kubo formulae deduced in chapter\footnote{\textsuperscript{1} However, as this requires commuting the $\gamma_5$ with the rest of the $\gamma$ matrices, only cutoff regularization can be applied.} to compute anomalous transport in a system of free chiral fermions. The anomalous magnetic conductivity has been derived and applied in \cite{21} whereas the one for the anomalous vortical conductivity has been established first in \cite{36}. They are

$$\sigma_{AB}^\mathbf{B} = \lim_{k_n \to 0} \sum_{ij} e_{ijn} \frac{-i}{2k_n} \langle J_A^i J_B^j \rangle \big|_{\omega = 0} ,$$

$$\sigma_A^\mathbf{V} = \lim_{k_n \to 0} \sum_{ij} e_{ijn} \frac{-i}{2k_n} \langle J_A^i T^{0j} \rangle \big|_{\omega = 0} ,$$

where $J_A^\mu$ are the (anomalous) currents and $T^{\mu \nu}$ is the energy momentum tensor.

We will now evaluate the Kubo formulae (6.16), (6.17) for a theory of $N$ free right-handed fermions $\Psi^f$ transforming under a global symmetry group $G$ generated by matrices $(T_A)^f_g$. We denote the generators in the Cartan subalgebra by $H_A$. Chemical potentials $\mu_A$ can be switched on only in the Cartan subalgebra. Furthermore the presence of the chemical potentials breaks the group $G$ to a subgroup $\hat{G}$. Only the currents that lie in the unbroken subgroup are conserved (up to anomalies) and participate in the hydrodynamics. The chemical potential for the fermion $\Psi^f$ is given by $\mu^f = \sum_A q_A^f \mu_A$, where we write the Cartan generator $H_A = q_A^f \mathbf{S}^f_8$ in terms of its eigenvalues, the charges $q_A^f$. The unbroken symmetry group $\hat{G}$ is generated by those matrices $T_{A \hat{g}}^f$ fulfilling

$$T_{A \hat{g}}^f \hat{g}^8 = \mu^f T_{A \hat{g}}^f .$$

\footnote{\textsuperscript{1} However, as this requires commuting the $\gamma_5$ with the rest of the $\gamma$ matrices, only cutoff regularization can be applied.}
6.2 Thermal two point functions

There is no summation over indices in the last expression. From now on we will assume that all currents \( \vec{J}_A \) lie in directions indicated in (6.18). We define the chemical potential through boundary conditions on the fermion fields around the thermal circle using formalism (B),

\[
\Psi_f^f(\tau) = -e^{\beta \mu_f^f} \Psi_f^f(\tau - \beta),
\]

(6.19)

with \( \beta = 1/T \). Therefore the eigenvalues of \( \partial_\tau \) are \( i \tilde{\omega}_n^f + \mu_f^f \) for the fermion species \( f \) with \( \tilde{\omega}_n = \pi T(2n + 1) \) the fermionic Matsubara frequencies \([75]\). A convenient way of expressing the currents is in terms of Dirac fermions and writing

\[
J_i^A = \sum_{f,g=1}^N T_{fg}^A \bar{\Psi}_g \gamma_i \gamma_0 \Psi_f + \Psi_f^\dagger \gamma_i \gamma_0 \bar{\Psi}_g^\dagger, \quad (6.20)
\]

\[
T_{0i} = i/2 \sum_{f=1}^N \bar{\Psi}_f (\gamma^0 \partial_i + \gamma^i \partial^0) \bar{\gamma}_f + \gamma_i \Psi_f, \quad (6.21)
\]

where we used the chiral projector \( \mathcal{P}_\pm = \frac{1}{2} (1 \pm \gamma_5) \). The fermion propagator is

\[
S(q)_{fg} = \frac{\delta_{fg}}{2} \sum_{t=\pm} \Delta_t (i \tilde{\omega}_t^f, \bar{q}) \mathcal{P}_+ \gamma_\mu \bar{q}_\mu, \quad (6.22)
\]

\[
\Delta_t (i \tilde{\omega}_t^f, q) = \frac{1}{i \tilde{\omega}_t^f - t E_q}, \quad (6.23)
\]

with \( i \tilde{\omega}_t^f = i \tilde{\omega}_n + \mu_f^f, \tilde{\omega}_n = (1,t \tilde{q}), \tilde{q} = \frac{q}{E_q} \) and \( E_q = |q| \). We can easily include left-handed fermions as well. They contribute in all our calculations in the same way as the right handed ones up to a relative minus sign.

6.2.1 Evaluation of Kubo formulas

We will address in detail the computation of the vortical conductivities Eq. (6.17) and sketch only the calculation of the magnetic conductivities since the latter one is a trivial extension of the calculation of the chiral magnetic conductivity in \([21]\).

Vortical conductivity

The vortical conductivity is defined from the retarded correlation function of the current \( J_A^i(x) \) (6.20), and the energy momentum tensor or energy current \( T_{0i}(x') \) (6.21), i.e.

\[
G_\Lambda^{\hat{Y}}(x-x') = \frac{1}{2} \epsilon_{ijn} i \theta (t-t') \langle [J_A^i(x), T_{0j}(x')] \rangle. \quad (6.24)
\]

Going to Fourier space, one can evaluate this quantity as

\[
G_\Lambda^{\hat{Y}}(k) = \frac{1}{4} \sum_{f=1}^N T_{fg}^f \int \frac{d^3 \bar{q}}{(2\pi)^3} \epsilon_{ijn} \text{tr} \left[ \bar{S}_f^f(q) \gamma_j S_f^f(q+k) \left( \gamma_i q_j^* + \gamma^i \tilde{\omega}_f^j \right) \right], \quad (6.25)
\]
Using Eqs. (6.27), (6.28) and (6.29) one can express \( G \) on the computation of \( A \). From a computation of the Dirac trace in Eq. (6.27) one has two contributions, i.e.

\[
G^V_A(k) = G^V_{A,(0j)}(k) + G^V_{A,(j0)}(k),
\]

which correspond to the terms \( \gamma^0 q^j \) and \( \gamma^j i \partial_x \) in Eq. (6.25) respectively. We will focus first on the computation of \( G^V_{A,(0j)} \). The integrand of Eq. (6.25) for \( G^V_{A,(0j)} \) can be written as

\[
J^V_{A,(0j)} = \frac{1}{4} q^j \sum_{t,u=\pm} \varepsilon_{ijn} \text{tr} [\gamma_\mu \gamma_\nu \gamma_\rho \gamma_0] \Delta_t (i \partial^\rho f, \vec{q}) \Delta_u (i \partial^\rho f + i \omega_n, \vec{q} + \vec{k}) q^\mu u (q + k)_\nu.
\]

From a computation of the Dirac trace in Eq. (6.27) one has two contributions

\[
\varepsilon_{ijn} \text{tr} [\gamma_\mu \gamma_\nu \gamma_\rho \gamma_0] a^t b^\nu = 4 \varepsilon_{ijn} (a^t b^0 + a^0 b^t),
\]

\[
\varepsilon_{ijn} \text{tr} [\gamma_\mu \gamma_\nu \gamma_\rho \gamma_5] a^t b^\nu = 4 i (a_j b_n - a_n b_j).
\]

Using Eqs. (6.27), (6.28) and (6.29) one can express \( G^V_{A,(0j)}(k) \) as

\[
G^V_{A,(0j)}(k) = \frac{1}{8} \sum_{f=1}^N T^f_A \int \frac{d^3 q}{(2\pi)^3} q^j \sum_{t,u=\pm} \varepsilon_{ijn} \left( t \frac{q^i}{E_q} + u \frac{k^i + q^i}{E_{q+k}} \right) + \frac{it}{E_q E_{q+k}} \left( q_j k_n - q_n k_j \right) \Delta_t (i \partial^j f, \vec{k}) \Delta_u (i \partial^j f + i \omega_n, \vec{q} + \vec{k}).
\]

At this point one can make a few simplifications. Note that due to the antisymmetric tensor \( \varepsilon_{ijn} \), the two terms proportional to \( q^j \) inside the bracket in Eq. (6.30) vanish. Regarding the term \( \varepsilon_{ijn} q^i k^j \), it leads to a contribution \( \sim \varepsilon_{ijn} k^j k^j \) after integration in \( d^3 q \), which is zero. Then the only term which remains is the one not involving \( \varepsilon_{ijn} \). We can now perform the sum over fermionic Matsubara frequencies. One has

\[
\frac{1}{\beta} \sum_{\omega_f} \Delta_t (i \partial^f, \vec{q}) \Delta_u (i \partial^f + i \omega_n, \vec{q} + \vec{p}) = \frac{tn(E_q - t \mu^f) - un(E_{q+k} - u \mu^f) + \frac{1}{2} (u - t)}{i \omega_n + t E_q - u E_{q+k}},
\]

Figure 6.2: 1 loop diagram contributing to the vortical conductivity Eq. (6.17).
where \( n(x) = 1/(e^{\beta x} + 1) \) is the Fermi-Dirac distribution function. In Eq. (6.31) we have considered that \( \omega_n = 2\pi T n \) is a bosonic Matsubara frequency. This result is also obtained in Ref. [21]. After doing the analytic continuation, which amounts to replacing \( i\omega_n \) by \( k_0 + i\varepsilon \) in Eq. (6.31), one gets

\[
G^\gamma_{A,(0j)}(k) = -\frac{i}{8} \sum_{f=1}^{N} T^f_A \int \frac{d^3q}{(2\pi)^3} \frac{q^2 k_n - (\vec{q} \cdot \vec{k}) q_n}{E_q E_{q+k}} \times \sum_{t,\nu = \pm} \frac{un(E_q - t\mu^f) - tn(E_{q+k} - u\mu^f) + \frac{1}{2}(t-u)}{k_0 + i\varepsilon + tE_q - uE_{q+k}}. 
\]

The term proportional to \( \sim \frac{1}{2}(t-u) \) corresponds to the vacuum contribution, and it is ultraviolet divergent. By removing this term the finite temperature and chemical potential behavior is not affected, and the result becomes ultraviolet finite because the Fermi-Dirac distribution function exponentially suppresses high momenta. By making both the change of variable \( \vec{q} \rightarrow -\vec{q} - \vec{k} \) and the interchange \( u \rightarrow -t \) and \( t \rightarrow -u \) in the part of the integrand involving the term \(-tn(E_{q+k} - u\mu^f)\), one can express the vacuum subtracted contribution of Eq. (6.32) as

\[
G^\gamma_{A,(0j)}(k) = -\frac{i}{8} k_n \sum_{f=1}^{N} T^f_A \int \frac{d^3q}{(2\pi)^3} \frac{1}{E_q E_{q+k}} \left( \frac{\vec{q}^2 - (\vec{q} \cdot \vec{k})^2}{k^2} \right) \times \sum_{t,\nu = \pm} \frac{n(E_q - \mu^f) + n(E_q + \mu^f)}{k_0 + i\varepsilon + tE_q + uE_{q+k}}. 
\]

where we have used that \( n(E_q - t\mu^f) + n(E_q + t\mu^f) = n(E_q - \mu^f) + n(E_q + \mu^f) \) since \( t = \pm 1 \). The result has to be proportional to \( k_n \), so to reach this expression we have replaced \( q_n \) by \( (\vec{q} \cdot \vec{k}) k_n / k^2 \) in Eq. (6.32). At this point one can perform the sum over \( u \) by using \( \sum_{\nu = \pm} u/(a_1 + a_2) = -2a_2/(a_1^2 - a_2^2) \), and the integration over angles. by considering \( \vec{q} \cdot \vec{k} = E_q E_kx \) and \( E_{q+k}^2 = E_q^2 + E_k^2 + 2E_q E_kx \), where \( x := \cos(\theta) \) and \( \theta \) is the angle between \( \vec{q} \) and \( \vec{k} \). Then one gets the final result

\[
G^\gamma_{A,(0j)}(k) = \frac{i}{16\pi^2} \frac{k_n}{k^2} (k^2 - k_0^2) \sum_{f=1}^{N} T^f_A \int_{0}^{\infty} dq q f^\gamma(q) \left[ 1 + \frac{1}{8qk} \sum_{t,\nu = \pm} [k_0^2 - k^2 + 4q(q + tk_0)] \right] \times \log \left( \frac{\Omega_t^2 - (q+k)^2}{\Omega_t^2 - (q-k)^2} \right), 
\]

where \( \Omega_t = k_0 + i\varepsilon + tE_q \), and

\[
f^\gamma(q) = n(E_q - \mu^f) + n(E_q + \mu^f). 
\]

The steps to compute \( G^\gamma_{A,(0j)} \) in Eq. (6.26) are similar. In this case the Dirac trace leads to a different tensor structure, in which the only contribution comes from the trace involving \( \gamma_5 \), i.e.

\[
\epsilon_{ijk} \text{tr} \left[ \gamma_\mu \gamma_\nu \gamma_\mu \gamma_5 \right] a^h b^v = 8i(a_n b_0 - a_0 b_n). 
\]
The sum over fermionic Matsubara frequencies involves an extra \( i \bar{\omega} f \). Following the same procedure as explained above, the vacuum subtracted contribution writes, i.e.

\[
\frac{1}{\beta} \sum \delta f \Delta(t \bar{\omega} f, q) \Delta u(i \bar{\omega} f + i \omega_n, q + \bar{\omega}) = \frac{1}{i \omega_n + i E_q - u E_{q+k} + u E_{q+k}} \left[ E_q n(E_q - t \mu f) - (E_{q+k} - u i \omega_n) n(E_{q+k} - u \mu f) - \frac{1}{2} (E_q - E_{q+k} + u i \omega_n) \right].
\]  

(6.37)

The last term inside the bracket in the r.h.s. of Eq. (6.37) corresponds to the vacuum contribution which we choose to remove, as it leads to an ultraviolet divergent contribution after integration in \( d^3 q \). Making similar steps as for \( \hat{G}_{A,0}^\gamma \), one finds the equation analogous to Eq. (6.33), which writes

\[
\hat{G}_{A,j0}^\gamma (k) = \frac{i}{4} \sum_{f=1}^{N} T_{A}^f \int \frac{d^3 q}{(2\pi)^3} \sum_{r,u=\pm} \left( \frac{t q_n + u q_n + k_n}{E_q} \right) \times \frac{E_q \left[ n(E_q - \mu f) + n(E_q + \mu f) \right] + t k_0 n(E_q + \mu f)}{k_0 + i \epsilon + t E_q + u E_{q+k}}.
\]  

(6.38)

After performing the sum over \( u \) and integrating over angles, one gets the final result

\[
\hat{G}_{A,j0}^\gamma (k) = -\frac{i}{32\pi^2 k^3} \sum_{f=1}^{N} T_{A}^f \int_{0}^{\infty} dq \sum_{t=\pm} f^\gamma_t (q, k_0) \times \left[ 4t q k_0 - (k^2 - k_0^2) (2q + t k_0) \log \left( \frac{\Omega_f^2 - (q+k)^2}{\Omega_f^2 - (q-k)^2} \right) \right],
\]  

(6.39)

where

\[
f^\gamma_t (q, k_0) = q f^\gamma (q) + t k_0 n(E_q + t \mu f).
\]  

(6.40)

The result for \( \hat{G}_{A}^\gamma (k) \) writes as a sum of Eqs. (6.34) and (6.39), according to Eq. (6.26). From these expressions one can compute the zero frequency, zero momentum, limit. Since

\[
\lim_{k \to 0} \lim_{k_0 \to 0} \sum_{t=\pm} \log \left( \frac{\Omega_f^2 - (q+k)^2}{\Omega_f^2 - (q-k)^2} \right) = \frac{2k}{q},
\]  

(6.41)

and

\[
\lim_{k \to 0} \lim_{k_0 \to 0} \sum_{t=\pm} \left[ k_0^2 - k^2 + 4q(q + t k_0) \right] \log \left( \frac{\Omega_f^2 - (q+k)^2}{\Omega_f^2 - (q-k)^2} \right) = 8qk,
\]  

(6.42)

the relevant integrals are

\[
\int_{0}^{\infty} dq q f^\gamma (q) = \int_{0}^{\infty} dq f^\gamma_t (q, k_0 = 0) = \frac{(\mu f)^2}{2} + \frac{\pi^2}{6} T^2.
\]  

(6.43)
Finally it follows from Eqs. (6.34) and (6.39) that the zero frequency, zero momentum, vortical conductivity writes

\[ \sigma^y_A = \frac{1}{8\pi^2} \sum_{f=1}^{N} T^f_A \left[ (\mu^f)^2 + \frac{\pi^2}{3} T^2 \right] \]

(6.44)

\[ = \frac{1}{16\pi^2} \left[ \sum_{B,C} \text{tr} (T_A \{ H_B, H_C \} \mu_B \mu_C + \frac{2\pi^2}{3} T^2 \text{tr} (T_A) \right] . \]

Both \( \tilde{G}^{y}_{A,(0j)} \) and \( \tilde{G}^{y}_{A,(j0)} \) lead to the same contribution in \( \sigma^y_A \). More interesting is the term \( \sim T^2 \) which is proportional to the gravitational anomaly [55, 76, 56] (see chapter 2). Left handed fermions contribute in the same way but with a relative minus sign.

If instead of having taken the zero momentum limit at zero frequency, one took the zero frequency limit at zero momentum, the result would be \( \frac{1}{3} \) of the result quoted in Eq. (6.44). The same factor appears in the magnetic conductivity when one interchanges the two limits [21].

**Magnetic conductivity**

The magnetic conductivity in the case of a vector and an axial \( U(1) \) symmetry was computed at weak coupling in [21]. Following the same method, we have computed it for the unbroken (non-abelian) symmetry group \( \hat{G} \). The relevant Green function is

\[ G^{B}_{AB} = \frac{1}{2} \sum_{f,g} T^f_A T^g_B \left[ \frac{1}{\beta} \sum_{i,j,n} \int \frac{d^3q}{(2\pi)^3} \epsilon_{ijn} \text{tr} \left[ S^f f(q) \gamma S^f f(q+k) \gamma^i \right] \right] . \]

(6.45)

The evaluation of this expression is exactly as in [21] so we skip the details. The result is

\[ \sigma^B_{AB} = \frac{1}{4\pi^2} \sum_{f,g=1}^{N} T^f_A T^g_B \left[ \frac{1}{8\pi^2} \sum_{C} \text{tr} (T_A \{ T_B, H_C \} \mu_C . \right] \]

(6.46)

In the second equality of Eq. (6.46) we have made use of Eq. (6.18). No contribution proportional to the gravitational anomaly coefficient is found in this case.

It is also interesting to specialize our results to the case of one vector and one axial current with chemical potentials \( \mu_R = \mu + \mu_5, \mu_L = \mu - \mu_5 \), charges \( q_{V,A}^R = (1,1) \) and \( q_{V,A}^L = (1,-1) \) for one right-handed and one left-handed fermion. We find (for a vector magnetic field)

\[ \sigma^B_{VV} = \frac{\mu s}{2\pi^2}, \quad \sigma^B_{AV} = \frac{\mu}{2\pi^2}, \]

\[ \sigma^V_{VV} = \frac{\mu \mu_s}{2\pi^2}, \quad \sigma^V_A = \frac{\mu^2 + \mu_5^2}{4\pi^2} + \frac{T^2}{12}. \]

(6.47)
Here $\sigma_{VV}^B$ is the chiral magnetic conductivity \[21\], $\sigma_{AV}^B$ describes the generation of an axial current due to a vector magnetic field \[12\], $\sigma_{VV}^V$ is the vector vortical conductivity in which the contributions of the gravitational anomaly cancel between right- and left-handed fermions. Finally $\sigma_{AV}^V$ is the axial vortical conductivity and it is this one that is sensitive to the presence of a gravitational anomaly.
In the previous chapter the general Kubo formulae \((4.80)\) were evaluated for a theory of free chiral fermions. The results showed a somewhat surprising appearance of the anomaly coefficient \(b_A\) for the gravitational anomaly. More precisely the chiral vortical conductivity for the symmetry generated by \(T_A\) was found to have two contributions, one depending only on the chemical potentials and proportional to the axial anomaly coefficient \(d_{ABC}\) and a second one with a characteristic \(T^2\) temperature dependence proportional to the gravitational anomaly coefficient \(b_A\).

The usage of Kubo formulae has here a clear advantage, it fixes all integration constants automatically. In this way it was possible in the previous chapter\(^1\) to show that the coefficient in front of the \(T^2\) term in the chiral vortical conductivity is essentially given by the gravitational anomaly coefficient \(b_A\). The disadvantage of Kubo formulae is of course that we have to calculate the potentially complicated correlations functions of a quantum field theory. They are easy to evaluate only in certain limits, such as the weak coupling limit considered in \([37]\). In principle the results obtained in this limit can suffer renormalization due to the model dependent interactions \([40, 41]\). The gauge-gravity correspondence \([2, 77, 78, 79]\) makes also the strong coupling limit easily accessible.

We would like to understand the effects anomalies have on the transport properties of relativistic fluids. Anomalies are very robust features of quantum field theories and do not depend on the details of the interactions. Therefore a rather general model that implements the correct anomaly structure in the gauge-gravity setup is sufficient for our purpose even without specifying in detail to which gauge theory it corresponds to. Our approach will therefore be a “bottom up” approach in which we simply add appropriate Chern-Simons terms that reproduce the relevant anomalies to the Einstein-Maxwell theory in five dimensions with

\(^1\)See \([37]\)
negative cosmological constant.\footnote{Very successful holographic bottom up approaches to QCD have been studied recently, either to describe non-perturbative phenomenology in the vacuum, see e.g. \cite{80, 81}, or the strongly coupled plasma \cite{82, 83, 84}.}

We will introduce a model that allows for a holographic implementation of the mixed gauge-gravitational anomaly via a mixed gauge-gravitational Chern-Simons term of the form

\[ S_{CS} = \int d^5 x \sqrt{-g} \varepsilon^{MNPQR} A_M R^A_{BNP} R^B_{AQR}. \]  

(7.1)

Gravity in four dimensions augmented by a similar term with a scalar field instead of a vector field has attracted much interest recently \cite{85} (see also the review \cite{86}). A four dimensional holographic model with such a term has been shown to give rise to Hall viscosity in \cite{87}. The quasinormal modes of this four dimensional model have been studied in \cite{88}.

### 7.1 Holographic Model

In this section we will define our model given the action

\[ S = \frac{1}{16\pi G} \int d^5 x \sqrt{-g} \left[ R - 2\Lambda - \frac{1}{4} F_{MN} F^{MN} + \varepsilon^{MNPQR} A_M \left( \frac{\kappa}{3} F_{NP} F_{QR} + \lambda R^A_{BNP} R^B_{AQR} \right) \right] + S_{GH} + S_{CSK}, \]  

(7.2)

\[ S_{GH} = \frac{1}{8\pi G} \int_\partial d^4 x \sqrt{-h} K, \]  

(7.3)

\[ S_{CSK} = -\frac{\lambda}{2\pi G} \int_\partial d^4 x \sqrt{-h} \varepsilon^{MNPQR} n_M A_N K_P L D_Q K_R, \]  

(7.4)

we define an outward pointing normal vector \( n_A \propto g^{AB} \frac{\partial \bar{r}}{\partial x^B} \) to the holographic boundary of an asymptotically AdS space with unit norm \( n_A n^A = 1 \) so that bulk metric can be decomposed as

\[ g_{AB} = h_{AB} + n_A n_B, \]  

(7.5)

where \( S_{GH} \) is the usual Gibbons-Hawking boundary term and \( D_A \) is the induced covariant derivative on the four dimensional hypersurface such that \( D_A h_{BC} = 0 \). The second boundary term \( S_{CSK} \) is needed if we want the model to reproduce the gravitational anomaly at general hypersurface.

In general a foliation with timelike surfaces defined through \( \bar{r}(x) = C \) can be written as

\[ ds^2 = (N^2 + N_\mu N^\mu) d\bar{r}^2 + 2N_\mu dx^\mu d\bar{r} + h_{\mu\nu} dx^\mu dx^\nu. \]  

(7.6)

To study the behavior of our model under the relevant gauge and diffeomorphism gauge symmetries we note that the action is diffeomorphism invariant. The Chern Simons terms
are well formed volume forms and as such are diffeomorphism invariant. They do depend however explicitly on the gauge connection $A_M$. Under gauge transformations $\delta A_M = \nabla_M \xi$ they are therefore invariant only up to a boundary term. We have

$$\delta S = \frac{1}{16\pi G} \int d^4x \sqrt{-h} \xi \varepsilon^{MNPQR} \left( \frac{\kappa}{3} n_M F_{NP} F_{QR} + \lambda n_M R^A_{\text{B}{NP}R^B_{\text{A}{QR}}} \right) + \frac{\lambda}{4\pi G} \int d^4x \sqrt{-h} n_M \varepsilon^{MNPQR} D_N \xi K_{PL} D_Q K^L_R. \quad (7.7)$$

This is easiest evaluated in Gaussian normal coordinates (see next section) where the metric takes the form $ds^2 = d\bar{r}^2 + h_{\mu\nu} dx^\mu dx^\nu$. All the terms depending on the extrinsic curvature cancel thanks to the contributions from $S_{CSK}$. The gauge variation of the action depends only on the intrinsic four dimensional curvature of the boundary and is given by

$$\delta S = \frac{1}{16\pi G} \int d^4x \sqrt{-h} \varepsilon^{\mu\nu\rho\lambda} \left( \frac{\kappa}{3} \hat{F}_{\mu\nu} \hat{F}_{\rho\lambda} + \lambda \hat{R}_{\mu\nu} \hat{R}_{\rho\lambda} \right). \quad (7.8)$$

This has to be interpreted as the anomalous variation of the effective quantum action of the dual field theory. The anomaly is therefore in the form of the consistent anomaly. Since we are dealing only with a single $U(1)$ symmetry the (gauge) anomaly is automatically expressed in terms of the field strength. We use this to fix $\kappa$ to the anomaly coefficient for a single chiral fermion transforming under a $U(1)_L$ symmetry. To do so we compare with (2.8), simply set $T_A = 1$ which fixes the anomaly coefficient $d_{ABC} = \frac{1}{2} \text{Tr}(T_A \{T_B, T_C\}) = 1$ and therefore

$$- \frac{\kappa}{48\pi G} = \frac{1}{96\pi^2}, \quad (7.9)$$

similarly we can fix $\lambda$ and find

$$- \frac{\lambda}{16\pi G} = \frac{1}{768\pi^2}. \quad (7.10)$$

As a side remark we note that the gravitational anomaly could in principle also be shifted into the diffeomorphism sector. This can be done by adding an additional (Bardeen like) boundary counterterm to the action

$$S_{ct} = \int d^4x \sqrt{-h} A_\mu I^\mu, \quad (7.11)$$

with $I^\mu = \varepsilon^{\mu\nu\rho\lambda} (\hat{\Gamma}_\nu^\alpha \partial_\rho \hat{\Gamma}_\lambda^\beta + \frac{2}{3} \varepsilon^{\delta\alpha\beta} \hat{\Gamma}_\rho^\delta \hat{\Gamma}_\lambda^\beta) - \frac{1}{4} \varepsilon^{\mu\nu\rho\lambda} \hat{R}_{\mu\nu} \hat{R}_{\rho\lambda}$. Since this term depends explicitly on the four dimensional Christoffel connection it breaks diffeomorphism invariance.

The bulk equations of motion are

$$G_{MN} + \Lambda g_{MN} = \frac{1}{2} F_{MN} F_N^L - \frac{1}{8} F^2 g_{MN} + 2\lambda \varepsilon_{LPQR(M} \nabla_B \left( F_{PL} R^B_{N) QR} \right), \quad (7.12)$$

$$\nabla_N F^N_{\text{MN}} = -\varepsilon^{MNPQR} \left( \kappa F_{NP} F_{QR} + \lambda R^A_{\text{B}{NP}R^B_{\text{A}{QR}}} \right), \quad (7.13)$$
and they are gauge and diffeomorphism covariant. We note that keeping all boundary terms in the variations that lead to the bulk equations of motion we end up with boundary terms that contain derivatives of the metric variation normal to the boundary. We will discuss this issue in more detail in the next section where we write down the Gauss-Codazzi decomposition of the action.

7.2 Holographic Renormalization

In order to go through the steps of the holographic renormalization program within the Hamiltonian approach [89, 90], first of all we establish some notations. Without loss of generality we choose a gauge with vanishing shift vector $N_{\mu} = 0$, lapse $N = 1$ and $A_{r} = 0$. In this gauge the bulk metric can be written as

$$ds^2 = d\bar{r}^2 + h_{\mu\nu}dx^{\mu}dx^{\nu}.$$  \hfill (7.14)

The non vanishing Christoffel symbols are

$$-\Gamma_{\mu\nu}^{\bar{r}} = K_{\mu\nu} = \frac{1}{2}h_{\mu\nu},$$  \hfill (7.15)
$$\Gamma_{\nu\bar{r}}^{\mu} = K_{\mu}^{\nu},$$  \hfill (7.16)

and $\hat{\Gamma}_{\nu\rho}^{\mu}$ are four dimensional Christoffel symbols computed with $h_{\mu\nu}$. Dot denotes differentiation respect $\bar{r}$. All other components of the extrinsic curvature vanish, i.e. $K_{\bar{r}\bar{r}} = K_{\bar{r}\mu} = 0$. Another useful table of formulas is

$$\hat{\Gamma}_{\mu\nu}^{\lambda} = D_{\mu}K_{\nu}^{\lambda} + D_{\nu}K_{\mu}^{\lambda} - D_{\lambda}K_{\mu\nu},$$  \hfill (7.17)
$$R_{\mu\nu\bar{r}}^{\bar{r}} = -\dot{K}_{\mu\nu} + K_{\mu\lambda}K_{\nu}^{\lambda},$$  \hfill (7.18)
$$R_{\mu\nu\bar{r}}^{\mu} = -\dot{K}_{\nu}^{\mu} - K_{\nu}\lambda K_{\lambda}^{\mu},$$  \hfill (7.19)
$$R_{\mu\nu\rho}^{\bar{r}} = D_{\nu}K_{\mu\rho} - D_{\rho}K_{\mu\nu},$$  \hfill (7.20)
$$R_{\mu\nu\bar{r}}^{\lambda} = D_{\mu}K_{\nu}^{\lambda} - D_{\lambda}K_{\nu\mu},$$  \hfill (7.21)
$$R_{\mu\nu\rho\lambda}^{\nu\rho\lambda} = \hat{R}_{\nu\rho\lambda} - K_{\rho}^{\mu}K_{\nu\lambda} + K_{\lambda}^{\mu}K_{\nu\rho}.$$  \hfill (7.22)

Note that indices are now raised and lowered with $h_{\mu\nu}$, e.g. $K = h_{\mu\nu}K_{\mu\nu}$, and intrinsic four dimensional curvature quantities are denoted with a hat, so $\hat{R}_{\nu\rho\lambda}$ is the intrinsic four dimensional Riemann tensor on the $\bar{r}(x) = C$ surface. Finally the Ricci scalar is

$$R = \hat{R} - 2\ddot{K} + K^{2} - K_{\mu\nu}K^{\mu\nu}.$$  \hfill (7.23)

Now we can calculate the off shell action. It is useful to divide it up in three terms. The first one is the usual gravitational bulk and gauge terms with the usual Gibbons-Hawking
term and the other two the gauge Chern Simons and the Mixed gauge-gravitational Chern Simons.

\[ S^0 = \frac{1}{16\pi G} \int d^5 x \sqrt{-h} \left[ \hat{R} - 2\Lambda + K^2 - K_{\mu\nu} K^{\mu\nu} - \frac{1}{2} E_{\mu} E^{\mu} - \frac{1}{4} \hat{F}_{\mu\nu} \hat{F}^{\mu\nu} \right], \quad (7.24) \]

\[ S^1_{CS} = -\frac{\kappa}{12\pi G} \int d^5 x \sqrt{-h} \epsilon^{\mu\nu\rho\lambda} A_\mu E_\nu \hat{F}_{\rho\lambda}, \quad (7.25) \]

\[ S^2_{CS} = -\frac{8\lambda}{16\pi G} \int d^5 x \sqrt{-h} \epsilon^{\mu\nu\rho\lambda} \left[ A_\mu \hat{R}^\alpha_{\beta\rho\lambda} D_\alpha K_\beta^\mu + E_\mu K_{\nu\alpha} D_\rho K^{\alpha}_{\lambda} + \frac{1}{2} \hat{F}_{\mu\rho} K_{\nu\alpha} K^{\alpha}_{\lambda} \right]. \quad (7.26) \]

We have used implicitly here the gauge \( A_\mu = 0 \) and denoted \( \dot{A}_\mu = E_\mu \). The purely four dimensional field strength is denoted with a hat.

Of particular concern is the last term in \( S^2_{CS} \) which contains explicitly the normal derivative of the extrinsic curvature \( \dot{K}_{\mu\nu} \). For this reason the field equations will be generically of third order in \( r \)-derivatives and that means that we can not define a well-posed Dirichlet problem by fixing the \( h_{\mu\nu} \) and \( K_{\mu\nu} \) alone but generically we would need to fix also \( \dot{K}_{\mu\nu} \). Having applications to holography in mind we will however impose the boundary condition that the metric has an asymptotically AdS expansion of the form

\[ h_{\mu\nu} = e^{2\bar{r}} \left[ g_{\mu\nu}^{(0)} + e^{-2\bar{r}} g_{\mu\nu}^{(2)} + e^{-4\bar{r}} (g_{\mu\nu}^{(4)} + 2\bar{r} g_{\mu\nu}^{(4)}) + \cdots \right]. \quad (7.27) \]

Using the on-shell expansion of \( K_{\mu\nu} \) obtained in the appendix [C.1] we can show that the last term in the action does not contribute in the limit \( r \to \infty \). Therefore the boundary action depends only on the boundary metric \( h_{\mu\nu} \) but not on the derivative \( h_{\mu\nu} \). This is important because otherwise the dual theory would have additional operators that are sourced by the derivative. Similar issues have arisen before in the holographic theory of purely gravitational anomalies of two dimensional field theories [87, 91, 92]. Alternatively one could restrict the field space to configurations with vanishing gauge field strength on the boundary. Then the last term in \( S^2_{CS} \) is absent. We note that the simple form of the higher derivative terms arises only if we include \( S_{CSK} \) in the action. An analogous term in four dimensional Chern-Simons gravity has been considered before in [93].

The renormalization procedure follows from an expansion of the four dimensional quantities in eigenfunctions of the dilatation operator

\[ \delta_D = 2 \int d^4 x h_{\mu\nu} \frac{\delta}{\delta h_{\mu\nu}}. \quad (7.28) \]

We explain in much details the renormalization in appendix [C.1]. The result one gets for the counterterm coming from the regularization of the boundary action is

\[ S_{ct} = -\frac{(d-1)}{8\pi G} \int d^4 x \sqrt{-h} \left[ -\frac{2\Lambda}{d(d-1)} + \frac{1}{(d-2)} P - \frac{1}{4(d-1)} \left( p_{\nu}^{\mu} p_{\nu}^{\mu} - p^2 - \frac{1}{4} \hat{F}_{\mu\nu} \hat{F}^{(0)\mu\nu} \right) \log e^{-2\bar{r}} \right], \quad (7.29) \]
where $d = 4$, $\bar{r}$, the UV cutoff and
\[
P = \frac{\hat{R}}{2(d - 1)}, \quad P^\mu = \frac{1}{(d - 2)} \left[ \hat{R}^\mu - P \delta^\mu \right].
\]

As a remarkable fact there is no contribution in the counterterm coming from the gauge-gravitational Chern-Simons term. This has also been derived in [94] in a similar model that does however not contain $S_{CSK}$.

### 7.3 Currents and Ward identities

As we discussed before the action is third order in $r$ derivatives, so in order to get the correct one point functions we have to take into account this fact and include the assumption that the bulk space is asymptotically anti-de Sitter. Asymptotically $AdS$ is enough to get a well defined boundary value problem just in terms of the field boundary theory sources. Let us analyze now what this implies for a general Lagrange density.

#### 7.3.1 The holographic dictionary with higher derivatives

Let us assume a general renormalized Lagrangian for an arbitrary set of fields that we will call $\phi$ after the four dimensional ADM decomposition\[3\]
\[
S = \int d^4x dr L(\phi, \dot{\phi}, D_\mu \phi, D_\mu \dot{\phi}, \ddot{\phi}),
\]

where dot indicates derivative with respect to the radial coordinate. A general variation of the action leads now to
\[
\delta S = \int_B d^4x dr \left[ \frac{\partial L}{\partial \phi} \delta \phi + \frac{\partial L}{\partial \dot{\phi}} \delta \dot{\phi} + \frac{\partial L}{\partial (D_\mu \phi)} \delta (D_\mu \phi) + \frac{\partial L}{\partial (D_\mu \dot{\phi})} \delta (D_\mu \dot{\phi}) + \frac{\partial L}{\partial \ddot{\phi}} \delta \ddot{\phi} \right].
\]

Through a series of partial integrations we can bring this into the following form,
\[
\delta S = \int d^4x dr E.O.M. \delta \phi + \int_{\partial_c} d^4x \left[ \left( \frac{\partial L}{\partial \phi} - D_\mu \left( \frac{\partial L}{\partial (D_\mu \phi)} \right) - \left( \frac{\partial L}{\partial \dot{\phi}} \right) \right) \delta \phi + \frac{\partial L}{\partial \dot{\phi}} \delta \dot{\phi} \right].
\]

The bulk terms are the equations of motion. For a generic boundary, the form of the variation shows that Dirichlet boundary conditions can not be imposed. Vanishing of the action rather imposes a relation between $\delta \phi$ and $\delta \dot{\phi}$.

If we have applications of holography in mind, there is however another way of dealing with the boundary term. We suppose now that we are working in an asymptotically anti-de

---

3For simplicity we will omit internal indices of the field $\phi$
Sitter space. The field $\phi$ has therefore a boundary expansion

$$\phi = e^{(\Delta-4)r} \phi^{(0)} + \text{subleading},$$

here $\Delta$ is the dimension (conformal weight) of the operator that is sourced by $\phi^{(0)}$. Since this is a generic property of holography in AdS spaces, we can relate the derivative of the variation to the variation itself,

$$\delta \phi = (\Delta - 4)e^{(\Delta-4)r} \delta \phi^{(0)} + \text{subleading}. $$

Using that, the consistent operator is defined as the variation of the on-shell action with respect to the source $\phi^{(0)}$. We find therefore

$$\sqrt{-h(0)} \mathcal{O}_\phi = \lim_{r \to r_*} e^{(\Delta-4)r} \left[ \frac{\partial L}{\partial \dot{\phi}} - D\mu \left( \frac{\partial L}{\partial (D\mu \phi)} \right) - \frac{d}{dr} \left( \frac{\partial L}{\partial \ddot{\phi}} \right) + (\Delta - 4) \left( \frac{\partial L}{\partial \dot{\phi}} \right) \right]. \tag{7.33} $$

From this we can compute the bare consistents $U(1)$ current and the energy-momentum tensor, and the result is

$$16\pi G^\mu_\nu = -\lim_{r \to r_*} \sqrt{-h} \left[ F_{\mu\nu} + \frac{4}{3} \kappa \epsilon^\mu_{\nu\rho\lambda} A_\nu \hat{F}_{\rho\lambda} \right], \tag{7.34} $$

$$8\pi G T_{(c)}^\mu_\nu = \lim_{r \to r_*} \sqrt{-h} \left[ K_{\mu\nu} - K^\alpha_{\nu\lambda} + 4\lambda \epsilon^{\mu\rho\lambda\beta} \left( \frac{1}{2} \hat{F}_{\alpha\beta} \hat{R}_{\nu\rho\lambda} + \nabla_\delta (A_\alpha \hat{R}_\delta \nu_{\rho\lambda}) \right) \right]. \tag{7.35} $$

Now taking the divergence of these expressions and using Codazzi form of the equations of motion shown in appendix B, we get the anomalous charge conservation and the energy-momentum conservation relations respectively,

$$D_\mu J^\mu = -\frac{1}{16\pi G} \epsilon^{\mu\nu\rho\lambda} \left( \kappa \hat{F}_{\mu\nu} \hat{F}_{\rho\lambda} + \lambda \hat{R}_\alpha \beta_{\mu\nu} \hat{R}^\beta_{\rho\lambda} \right), \tag{7.36} $$

$$D_\mu T_{(c)}^\mu_\nu = \hat{F}^{\nu\mu} \gamma_\mu + A_\nu D_\mu \gamma^\mu. \tag{7.37} $$

These are precisely the consistent Ward identities for a theory invariant under diffeomorphisms with a mixed gauge gravitational anomaly plus a pure gauge anomaly.

We have computed the currents as the derivative of the field theory quantum action, and the anomaly is therefore in the form of the consistent anomaly. However it is always possible to add a Chern-Simons current and redefine the charge current $J^\mu \to J^\mu + c \epsilon^{\mu\nu\rho\lambda} A_\nu \hat{F}_{\rho\lambda}$, and the energy-momentum tensor $T^{\mu\nu} \to T^{\mu\nu} + c' \epsilon^{\alpha\mu\rho\lambda} \nabla_\alpha (A_\alpha R^{\mu\nu})_{\rho\lambda}$. These redefined quantities can not be expressed as the variation of a local functional of the fields with respect to the gauge and metric fields respectively. In particular the so-called covariant form of the anomaly differs precisely in such a redefinition of the current.\footnote{Note that the effective field theory hydrodynamic approaches used in \cite{33} and in subsequent works, typically make use of the covariant form of the anomaly \cite{34}.} Finally we can write the
covariant expressions for the current and energy-momentum tensor which are the ones that satisfy (2.22) and (2.21).

\[
16\pi G J^\mu = -\lim_{r \to r_*} \frac{\sqrt{-h}}{\sqrt{-g^{(0)}}} F_{r^\mu}^r, \quad (7.38)
\]

\[
8\pi G T^{\mu\nu} = \lim_{r \to r_*} \frac{\sqrt{-h}}{\sqrt{-g^{(0)}}} \left[ K^{\mu\nu} - K h^{\mu\nu} + 2\lambda \varepsilon^{\mu \alpha \beta \rho} \tilde{F}_{\alpha \beta} K_{\rho}^{\nu} \right], \quad (7.39)
\]

Of course these one point functions either in their consistent or covariant form have to be renormalized in order to make sense, so is necessary to include the contributions coming from the counterterm (7.29) and then take the limit \( r_* \to \infty \).

### 7.4 Kubo formulae, anomalies and chiral vortical conductivity

We are now going to evaluate the Kubo formulas for anomalous transport in our holographic model. We will do that in the same way as we did it in chapter 5. Since we are interested in the linear response limit, we split the metric and gauge field into a background part and a linear perturbation:

\[
g_{MN} = g_{MN}^{(0)} + \varepsilon h_{MN}, \quad (7.40)
\]

\[
A_M = A_M^{(0)} + \varepsilon a_M. \quad (7.41)
\]

Inserting these fluctuations-background fields in the action and expanding up to second order in \( \varepsilon \) we can read the second order action which is needed to get the desired propagators.

The system of equations (7.12)-(7.13) admit the following exact background AdS Reissner-Nordström black-brane solution

\[
d s^2 = \frac{r^2}{L^2} \left(-f(r) dt^2 + d\vec{x}^2\right) + \frac{L^2}{r^2 f(r)} dr^2,
\]

\[
A^{(0)} = \phi(r) dt = \left( \beta - \frac{\mu r^2}{r^2} \right) dt, \quad (7.42)
\]

where the horizon of the black hole is located at \( r = r_+ \), the cosmological constant is \( \Lambda = -6/L^2 \) and the blackening factor of the metric is

\[
f(r) = 1 - \frac{m L^2}{r^4} + \frac{q^2 L^2}{r^6}. \quad (7.43)
\]

Do not confuse the background metric here \( g_{MN}^{(0)} \) with the boundary metric used in the asymptotic expansion above.
The parameters $M$ and $Q$ of the RN black hole are related to the chemical potential $\mu$ and the horizon $r_H$ by

$$m = \frac{r_H^4}{L^2} + \frac{q^2}{r_+^2}, \quad q = \frac{\mu r_+^2}{\sqrt{3}}.$$  

(7.44)

The Hawking temperature is given in terms of these black hole parameters as

$$T = \frac{r_H^2}{4\pi L^2} f(r_+)' = \frac{(2r_+^2 m - 3q^2)}{2\pi r_+^5}.$$  

(7.45)

The pressure of the gauge theory is $P = \frac{m}{16\pi G L^3}$ and its energy density is $\varepsilon = 3P$ due to the underlying conformal symmetry.

Without loss of generality we consider perturbations of momentum $k$ in the $y$-direction at zero frequency. To study the effect of anomalies we just turned on the shear sector (transverse momentum fluctuations) $a_a$ and $h_a^t$, where $a, b \ldots = x, z$. For convenience we redefine new parameters and radial coordinate

$$\tilde{\lambda} = \frac{4\mu \lambda L}{r_H^2}; \quad \tilde{\kappa} = \frac{4\mu \kappa L^3}{r_H^2}; \quad a = \frac{\mu^2 L^2}{3r_+^2}; \quad u = \frac{r_+^2}{r_H^2}. \quad (7.46)$$

Now the horizon sits at $u = 1$ and the AdS boundary at $u = 0$. Finally we can write the system of differential equations for the shear sector, that consists on four second order equations. Since we are interested in computing correlators at hydrodynamics regime, we will solve the system up to first order in $k$. The reduced system can be written as

\begin{align*}
0 &= \frac{h_a^{\mu}(u)}{u} - \frac{h_a^{\mu}(u)}{u} - 3auB_a(u) + i\tilde{\lambda} k \varepsilon_{ab} \left[ 2(24au^3 - 6(1 - f(u))) \frac{B_b(u)}{u} 
+ (9au^3 - 6(1 - f(u)))B_b(u) + 2u(auh_c^b(u))' \right], \\ 0 &= B_a'(u) + \frac{f'(u)}{f(u)} B_a(u) - \frac{h_a^{\mu}(u)}{f(u)} 
+ i\varepsilon_{ab} \left[ \frac{3}{u f(u)} \tilde{\lambda} \left( \frac{2}{a}(f(u) - 1) + 3u^3 \right) \frac{h_b^\mu(u)}{f(u)} + \tilde{\kappa} B_b(u) \right], 
\end{align*}

(7.47)

(7.48)

with the gauge field redefined as $B_a = a_a/\mu$, do not confuse this $B$-field with the magnetic field!. The complete system of equations depending on frequency and momentum is showed in appendix \[D\]. This system consists of six dynamical equations and two constraints.

In order to get solutions at first order in momentum we expand the fields in the dimensionless momentum $p = k/4\pi T$ such as

\begin{align*}
\hat{h}_i^{\mu}(u) &= \hat{h}_i^{(0)\mu}(u) + p \hat{h}_i^{(1)\mu}(u), \\
 \hat{B}_a(u) &= \hat{B}_a^{(0)}(u) + p \hat{B}_a^{(1)}(u).
\end{align*}

(7.49)

(7.50)

\[6\] Since we are in the zero frequency case the fields $\hat{h}_i^{\mu}$ completely decouple of the system and take a constant value, see appendix \[D\].
The relevant physical boundary conditions on fields are: $h_0(t) = \tilde{H}_a$, $B_a(0) = \tilde{B}_a$; where the ‘tilde’ parameters are the sources of the boundary operators. The second condition compatible with the ingoing one at the horizon is regularity for the gauge field and vanishing for the metric fluctuation (see Appendix F for a discussion on boundary conditions and frame selection in the field theory side) [36].

After solving the system perturbatively (see appendix E for solutions), we can go back to the formula (5.23) and compute the corresponding holographic Green’s functions. If we consider the vector of fields to be

$$\Phi_k^\top(u) = (B_x(u), h_x^t(u), B_z(u), h_z^t(u)), \quad (7.51)$$

the $A$ and $B$ matrices for that setup take the following form

$$A = \frac{r^4}{16\pi GL^5} \text{Diag} \left( -3af, \frac{1}{u}, -3af, \frac{1}{u} \right), \quad (7.52)$$

$$B_{AdS+\partial} = \frac{r^4}{16\pi GL^5} \begin{pmatrix} 0 & -3a & \frac{4\kappa_ik^2\phi L^5}{3r_+^2} & 0 \\ -\frac{3}{u^2} & 0 & 0 & 0 \\ \frac{4\kappa_ik^2\phi L^5}{3r_+^2} & 0 & 0 & -3a \\ 0 & 0 & 0 & -\frac{3}{u^2} \end{pmatrix}, \quad (7.53)$$

$$B_{CT} = \frac{r^4}{16\pi GL^5} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \frac{3}{u^2\sqrt{f}} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \frac{3}{u^2\sqrt{f}} \end{pmatrix}, \quad (7.54)$$

where $B = B_{AdS+\partial} + B_{CT}$. Notice that there is no contribution to the matrices coming from the Chern-Simons gravity part, the corresponding contributions vanish at the boundary. These matrices and the perturbative solutions are the ingredients to compute the matrix of propagators. Undoing the vector field redefinition introduced in (7.47) and (7.48) the
non-vanishing retarded correlation functions at zero frequency are then

\[
G_{x,tz} = G_{z,tz} = \frac{\sqrt{3} q}{4\pi GL^3}, \tag{7.55}
\]

\[
G_{x,z} = -G_{z,x} = i\frac{\sqrt{3} k q \kappa}{2\pi G r^4_+} + \frac{ik \beta \kappa}{6\pi G}, \tag{7.56}
\]

\[
G_{x,tz} = G_{t,z} = -G_{z,tx} = -G_{t,z} = \frac{3ik q^2 \kappa}{4\pi G r^4_+} + \frac{2ik \lambda \pi T^2}{G}, \tag{7.57}
\]

\[
G_{tx,tx} = G_{r,tz} = \frac{m}{16\pi GL^3}, \tag{7.58}
\]

\[
G_{tx,tz} = -G_{t,z,tx} = \frac{i\sqrt{3} k q^3 \kappa}{2\pi G r^6_+} + \frac{4\pi i\sqrt{3} k q T^2 \lambda}{Gr^2_+}. \tag{7.59}
\]

Using the Kubo formulae 4.80 and setting the deformation parameter \( \beta \) to zero we recover the conductivities

\[
\sigma_B = -\frac{\sqrt{3} q \kappa}{2\pi G r^4_+} = \frac{\mu}{4\pi^2}, \tag{7.60}
\]

\[
\sigma_V = \sigma_B^\varepsilon = -\frac{3q^2 \kappa}{4\pi G r^4_+} - \frac{2\lambda \pi T^2}{G} = \frac{\mu^2}{8\pi^2} + \frac{T^2}{24}, \tag{7.61}
\]

\[
\sigma_V^\varepsilon = -\frac{\sqrt{3} q^3 \kappa}{2\pi G r^6_+} - \frac{4\pi \sqrt{3} q T^2 \lambda}{Gr^2_+} = \frac{\mu^3}{12\pi^2} + \frac{\mu T^2}{12}. \tag{7.62}
\]

The first expression is in perfect agreement with the literature and the second one shows the extra \( T^2 \) term predicted in [37] and shown in the previous chapter. In fact the numerical coefficients coincide precisely with the ones obtained in weak coupling. We also point out that the \( T^3 \) term that appears as undetermined integration constant in the hydrodynamic considerations in [95] should make its appearance in \( \sigma_V^\varepsilon \). We do not find any such term which is consistent with the argument that this term is absent due to CPT invariance.

It is also interesting to write down the vortical and magnetic conductivity as they appear in the Landau frame,

\[
\xi_B = -\frac{\sqrt{3} q(mL^2 + 3r^4_\lambda) \kappa}{8\pi GmL^2 r^2_+} + \frac{\sqrt{3} q \lambda \pi T^2}{Gm} = \frac{1}{4\pi^2} \left( \mu - \frac{1}{2} \frac{n(\mu^2 + \frac{\pi^2 T^2}{3})}{\varepsilon + P} \right), \tag{7.63}
\]

\[
\xi_V = -\frac{3q^2 \kappa}{4\pi GmL^2} - \frac{2\pi \lambda T^2 (r^4_+ - 2L^2 q^2)}{GmL^2 r^2_+} = \frac{\mu^2}{8\pi^2} \left( 1 - \frac{2}{3} \frac{n\mu}{\varepsilon + P} \right) + \frac{T^2}{24} \left( 1 - \frac{2n\mu}{\varepsilon + P} \right). \tag{7.64}
\]
Finally let us also note that the shear viscosity is not modified by the presence of the gravitational anomaly. We know that $\eta \propto \lim_{w \to 0} \frac{1}{w} < T^{xy} T^{xy} >_{k=0}$, so we should solve the system at $k = 0$ for the fluctuations $h'_y$ but the anomalous coefficients always appear with a momentum $k$ as we can see in (D.3), therefore if we switch off the momentum, the system looks precisely as the theory without anomalies. In [96] it has been shown that the black hole entropy doesn’t depend on the extra mixed Chern-Simons term, therefore the shear viscosity entropy ratio remain the same in this model.

### 7.4.1 Frequency dependence

In order to study the frequency dependence of the chiral conductivities, we can use Eq. (4.80) to define

$$
\sigma_B(\omega) = \lim_{k_m \to 0} \frac{-i}{k_m} \varepsilon_{mij} \left\langle J^i J^j \right\rangle, \quad (7.65)
$$

$$
\sigma_V(\omega) = \lim_{k_m \to 0} \frac{-i}{k_m} \varepsilon_{mij} \left\langle J^{\mu} T_{\mu}^{j} \right\rangle. \quad (7.66)
$$

It is important to notice that these, and not the $\xi_V$ and $\xi_B$, are the relevant conductivities at finite frequency. The latter correspond to the conductivities measured in the local rest frame of the fluid, where one subtracts the contribution to the current due to the energy flux generated when we put the system in a background magnetic or vorticity field. But as we have seen, there is an ambiguity in the definition of the local rest frame: the fluid velocity is frequency and momentum dependent, one can just define it order by order in the hydrodynamic gradient expansion up to an arbitrary contribution. This automatically implies that the $\xi_V$ and $\xi_B$ are only meaningful in the zero frequency limit. On the other hand, the $\sigma_V$ and $\sigma_B$ conductivities are not subject to this problem: they capture the complete response of the system to the external magnetic fields. Therefore, it is sensible to define the frequency dependent chiral conductivities above, in an analogous way as for the A.C. electric conductivity.

To study that dependence holographically, we have to resort to numerics. The nature of the system allows us to integrate from the horizon out to the boundary, so we should fix boundary conditions at the first one, even though we would like to be free to fix the AdS boundary values of the fields, hence the operator sources. Imposing infalling boundary conditions, the fluctuations can be written as

$$
h'_y(u) = (1 - u)^{-iw+1} H'_y(u), \quad (7.67)
$$

$$
h'_x(u) = (1 - u)^{-iw} H'_x(u), \quad (7.68)
$$

$$
B^c(u) = (1 - u)^{-iw} b^c(u), \quad (7.69)
$$

\footnote{For a four dimensional holographic model with gravitational Chern-Simons term and a scalar field this has also been shown in [88].}
where \( w = \omega / 4\pi T \). As we saw, the remaining gauge symmetry acting on the shear channel implies that \( h^c_t \) and \( h^c_x \) are not independent. So if we fix the horizon value of the \( \{ b^c, H^c \} \) fields, the constraints (D.4) fixes
\[
H^a_t(1) = -\frac{3ia(1 + 384(-2 + a)^2(-2 + 3a)p^2\lambda^2)}{(2 - a)p - 768a(2 - a)^3p^3\lambda^2}b^a_t(1) - \frac{(i + w)}{(2 - a)p}H^a_t(1) + 24\sqrt{3a\lambda}\epsilon_{ab} \frac{(2 - 5a)}{1 - 768a(2 - a)^2p^2\lambda^2}b^b(1).
\] (7.70)

In order to find a maximal set of linearly independent solutions, we can construct four of them using linearly independent combinations of these horizon free parameters. In this way we construct the following independent horizon valued vectors
\[
\begin{pmatrix}
1 \\
0 \\
-\frac{3ia(1 + 384(-2 + a)^2(-2 + 3a)p^2\lambda^2)}{(2 - a)p - 768a(2 - a)^3p^3\lambda^2} \\
0 \\
-\frac{24\sqrt{3(2 - 5a)}\sqrt{a\lambda}}{1 - 768(2 - a)^2p^2\lambda^2}
\end{pmatrix},
\begin{pmatrix}
0 \\
1 \\
\frac{(i + w)}{(2 - a)p} \\
0
\end{pmatrix},
\begin{pmatrix}
0 \\
0 \\
0 \\
\frac{24\sqrt{3(2 - 5a)}\sqrt{a\lambda}}{1 - 768(2 - a)^2p^2\lambda^2}
\end{pmatrix},
\begin{pmatrix}
0 \\
0 \\
0 \\
\frac{3ia(1 + 384(-2 + a)^2(-2 + 3a)p^2\lambda^2)}{(2 - a)p - 768a(2 - a)^3p^3\lambda^2}
\end{pmatrix}
\] (7.71)

The remaining two are given by pure gauge solutions arising from gauge transformations of the trivial one. We choose them to be
\[
\Phi(u) = \begin{pmatrix}
0 \\
w \\
-p \\
0
\end{pmatrix},
\begin{pmatrix}
0 \\
0 \\
w \\
-p
\end{pmatrix}
\] (7.72)

Using the corresponding solutions we construct the \( F \) matrix of (5.22) in this way:
\[
F^I_J(u) = H^I_M(u)H^{-1M}_J(0),
\] (7.73)

where \( H^I_J(u) = (\Phi^I(u))_J \), for the numerical computation we used the numerical values \( \kappa = 1 \) and \( \lambda = 1/24 \) since we know that for a single chiral fermion the ratio \( \lambda / \kappa = 1/24 \) (see (7.9) and (7.10)).
Figure 7.1: Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency at $\tau = 36.5$ (left) and $\tau = 0.24$ (right). Red dotted points represent real part and thick blue line the imaginary conductivity.

In Figure 7.1 is illustrated the behavior of the vortical and magnetic conductivities as a function of frequency for two very different values of the dimensionless temperature $\tau = 2\pi r_+ T / \mu$. Both of them go to their corresponding zero frequency analytic result in the $\omega \to 0$ limit. The frequency dependent chiral magnetic conductivity was also computed in [47], though in that case the possible contributions coming from metric fluctuations were neglected. Our result for $\sigma_B(\omega)$ agrees pretty well with the result found in that work in the case of high temperature when the metrics fluctuations can be neglected and $\lambda = 0$ (see Appendix G), but it develops a dip close to $\omega = 0$ when temperature is decreased (see Figure 7.2), due to the energy flow effect. For small temperatures, the chiral magnetic conductivity drops to $\sim 1/3$ of its zero frequency value as soon as we move to finite frequency. The presence of the gravitational anomaly slightly introduce a dip close to $\omega = 0$ also in the case of high temperature. In Appendix G we can see how the kappa contribution is dominant for high and slow temperature in the chiral magnetic conductivity. The behaviour of $\sigma_V$ is slightly different: the damping is much faster and the imaginary part remains small compared with the zero frequency value. But unlike to the chiral magnetic conductivity, at high temperature the dominant contribution to the conductivity $\sigma_V$ comes from the $\lambda$-term and at slow enough temperature the pure gauge anomaly is dominant (see also Appendix G).
Figure 7.2: Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency close to $\omega = 0$. Real (left) and imaginary (right) part of the normalized conductivity for different values of the dimensionless temperature.

In Figure 7.2 we made a zoom to smaller frequencies in order to see the structure of the dip on $\sigma_B$ and the faster damping on $\sigma_V$. In Figure 7.3 we show the conductivities for very small temperature. From this plots we can infer that at zero temperature the conductivities behave like $\sigma_B = \alpha \sigma_B^0 \left( 1 + \frac{1-\alpha}{\omega} \delta(\omega) \right)$ and $\sigma_V = \sigma_V^0 \delta(\omega)$ with $\alpha$ a constant value of order $1/3$.

Figure 7.3: Chiral vortical (left) and magnetic (right) conductivities as function of the frequency at $\tau = 0.008$. Red dotted points represent real part and thick blue line the imaginary conductivity. The real part of $\sigma_V$ at $\omega = 0$ is outside the range of the plot.
The fluid/gravity correspondence is a very powerful tool to understand the hydrodynamic regime of quantum field theories with holographic dual. This technique has contributed to the understanding of the positivity of the entropy production using techniques of black hole thermodynamics \[97, 63, 98\]. It is also very useful for the computation of transport coefficients. In this chapter we will use this duality introduced in \[30\] and based on the AdS/CFT correspondence to compute all the second order transport coefficients of the model introduced in the previous section \[99\].

### 8.1 Fluid/Gravity Computation

As we saw above the system of bulk equations of motion \(\ref{7.12}\) and \(\ref{7.13}\) admits an AdS Reissner-Nordström black-brane solution of the form\(^1\)

\[
\begin{align*}
    ds^2 &= -r^2 f(r) dt^2 + \frac{dr^2}{r^2 f(r)} + r^2 dx^i dx^i, \\
    A &= \phi(r) dt,
\end{align*}
\]  
(8.1)

with \(f(r) = 1 - m/r^4 + q^2 / r^6\) and \(\phi(r) = -\sqrt{3} q / r^2\). The real and positive zeros of \(f(r)\) are

\[
\begin{align*}
    r_+ &= \frac{\pi T}{2} \left( 1 + \sqrt{1 + \frac{2}{3\pi^2} \bar{\mu}^2} \right), \\
    r_-^2 &= \frac{1}{2} r_+^2 \left( -1 + \sqrt{9 - \frac{8}{\frac{1}{2} \left( 1 + \sqrt{1 + \frac{2}{3\pi^2} \bar{\mu}^2} \right)^2} \right),
\end{align*}
\]  
(8.3)

\(\text{We have set } L=1\)
where $r_+$ is the outer horizon and $r_-$ the inner one. The mass of the black hole can be written in terms of hydro variables as

$$m = \frac{\pi^4 T^4}{2^4} \left( -1 + 3 \sqrt{1 + \frac{2}{3\pi^2 \tilde{\mu}^2}} \right).$$

(8.5)

The boosted version of this black hole in Eddington-Finkelstein coordinates looks like

$$ds^2 = -r^2 f(r) u_{\mu} u_{\nu} dx^\mu dx^\nu + r^2 P_{\mu\nu} dx^\mu dx^\nu - 2 u_{\mu} dx^\mu dr,$$

(8.6)

$$A = -\phi(r) u_{\mu} dx^\mu,$$

(8.7)

with the normalization condition $u_{\mu} u^{\mu} = -1$. The fluid/gravity approach tells us that we have to promote all the parameters to slow varying functions of the space time coordinates, and include corrections to the metric in order to make it a solution of the equations of motion again, for a good review see [100].

In order to follow the fluid/gravity techniques [30, 101, 32, 31] we will use a Weyl invariant formalism [102] in which the extraction of the transport coefficients is direct. We start with the ansatz

$$ds^2 = -2W_1(\rho) u_{\mu} dx^\mu \left( dr^2 + r A_{\nu} dx^\nu \right) + r^2 \left[ W_2(\rho) \eta_{\mu\nu} + W_3(\rho) u_{\mu} u_{\nu} + 2 \frac{W_4(\rho)}{r_+} P^{\sigma}_{\mu} u_{\nu} \right. \left. \right.$$  

$$+ \left. \frac{W_5(\rho)}{r_+^2} \right] dx^\mu dx^\nu,$$

(8.8)

$$A = \left( a_{(b)} + a_{(b)}(\rho) P^{\mu}_{\nu} + r_+ c(\rho) u_{\nu} \right) dx^\nu,$$

(8.9)

where $r_+$ is an unknown function $r_+(x)$ and coincide with the radius of the outer horizon of the black hole (Eq. (8.1)) when the $x^\mu$ dependence is gone. Notice that $\eta_{\mu\nu}$ is the Minkowski metric and $P^{\mu}_{\nu}$ is the projector defined in Eq. (4.8) built up with it, so we will look for metric solutions with flat boundary. The $r$-coordinate has Weyl weight $+1$, in consequence $r_+$ has the same property. By construction the $W$’s are Weyl invariant, then they will depend on $r$ only in a Weyl invariant way, i.e. $W(r) \equiv W(\rho)$ with $\rho = r/r_+$. $W_{\mu\nu}(r)$ obeys the traceless and transversality conditions $W_5(\rho) = 0$, $\mu^{\mu} W_{\mu\nu}(r) = 0$. All these scalars, vectors and tensors will be understood in term of a derivative expansion in the transverse coordinates, i.e. $F(\rho) = F^{(0)}(\rho) + \varepsilon F^{(1)}(\rho) + \varepsilon^2 F^{(2)}(\rho) + O(\varepsilon^3)$ for a generic function $F$, with $\varepsilon$ a parameter counting the number of boundary space-time derivatives. This solution leads to the current and energy momentum tensor after using the AdS/CFT dictionary (see Eqs.(7.34))

\footnote{This function $F(\rho)$ is basically a Taylor expansion around the point $s_0^\mu$.}
and \( T_{\mu \nu} \) from the counterterm of the action (7.29). They write

\[
T_{\mu \nu} = \frac{1}{16 \pi G} \lim_{\varepsilon_\ast \to 0} \left( r_0^\ast (W_2 + W_3)(\varepsilon_\ast) (4 u_\mu u_\nu + \eta_\mu \eta_\nu) + 4 r_0^2 W_{5\mu \nu} + 8 r_0^3 W_{4\sigma}^\ast P_{\mu \nu}^\ast + T_{\mu \nu}^{ct} \right),
\]

(8.11)

where \( F^{(\varepsilon_\ast)}(\varepsilon_\ast) \) denotes the coefficient of the term \((\rho^{-1} - \varepsilon_\ast)^n\) in an expansion around the regularized boundary, and \( \frac{1}{\varepsilon_\ast} \) is the UV cut-off. The counterterms in the current \( J_{\mu}^{ct} \) and energy momentum tensor \( T_{\mu \nu}^{ct} \) are needed to make the expressions finite, and they follow from the counterterm of the action (7.29). They write

\[
J_{\mu}^{ct} = \frac{1}{2} \log \varepsilon_\ast \left[ (2 \omega_\nu B^\nu - D_\nu E^\nu) u_\mu + \beta_\mu^{(7)} - \beta_\mu^{(10)} - \beta_\mu^{(5)} + \beta_\mu^{(6)} \right],
\]

(8.12)

\[
T_{\mu \nu}^{ct} = \log \varepsilon_\ast \left[ - \frac{1}{6} (B_{\alpha} B^\alpha + E_{\alpha} E^\alpha) P_{\mu \nu} - \frac{1}{2} (E_{\alpha} E^\alpha + B_{\alpha} B^\alpha) u_\mu u_\nu + J_{\mu \nu}^{(9)} + J_{\mu \nu}^{(10)} \right. \\
\left. \quad - (J_{\mu}^{(9)} u_\nu + J_{\nu}^{(9)} u_\mu) \right].
\]

(8.13)

We are considering a flat background metric, and so the divergences appear only through terms involving electromagnetic fields, in addition to the cosmological constant contribution which was already taken into account in Eq. (8.11).

The functions at zeroth order in the derivative expansion correspond to the boosted charged blackhole, i.e.\(^3\)

\[
c^{(0)}(\rho) = - \frac{\phi(\rho)}{r_+},
\]

(8.14)

\[
W_1^{(0)}(\rho) = 1 = W_2^{(0)}(\rho),
\]

(8.15)

\[
W_3^{(0)}(\rho) = 1 - f(\rho),
\]

(8.16)

\[
W_4^{(0)}(\rho) = 0 = W_5^{(0)}(\rho),
\]

(8.17)

\[
a_\mu^{(0)}(\rho) = 0.
\]

(8.18)

Then the charge current and energy momentum tensor at this order read \([31][32]\).

\[
J_{\mu}^{(0)} = \frac{\sqrt{3} q}{8 \pi G} u_\mu, \quad T_{\mu \nu}^{(0)} = \frac{m}{16 \pi G} (4 u_\mu u_\nu + \eta_\mu \eta_\nu) .
\]

(8.19)

From this we obtain the equilibrium pressure and charge density \( p = \frac{m}{16 \pi G} \) and \( n = \frac{\sqrt{3} q}{8 \pi G} \). For computational reasons it is convenient to define a Weyl invariant charge \( Q = q/r_+^3 \) and mass

\(^3\)Following the notation in [31], barred superscripts \((\bar{\eta})\) should not be confused with superscripts \((n)\), where the latter refers to the order in the hydrodynamical expansion.
Second Order Transport

\[ M = m/r_+^4 = 1 + Q^2. \] In terms of these redefined parameters, the black hole temperature and chemical potential read

\[ T = \frac{r_+}{2\pi}(2 - Q^2), \quad (8.20) \]

\[ \mu = \sqrt{3}r_+Q. \quad (8.21) \]

We also define the interior horizon in the \( \rho \)-coordinate \( \rho_2 \equiv r_-/r_+ \).

### 8.1.1 Einstein-Maxwell equations of motion and Ward identities

Inserting this ansatz into the Einstein-Maxwell system of equations we find a set of \( (2 \times 1 + 2 \times 3 + 5) \) differential equations and \( (2 \times 1 + 3) \) constraints relating the allowed \( Q(x^\mu) \), \( r_+(x^\mu) \), \( u^\nu(x^\mu) \) and \( A_\nu(x^\mu) \). We need to solve the e.o.m. about a certain point \( x_0^\mu = 0 \). At such point we sit in a frame in which \( u^\mu = (1, 0, 0, 0) \) and \( A_\mu(0) = 0 \).

The scalar sector is obtained from the \( rr \), \( rv \) and \( vv \) components of the Einstein equations, and the \( r \) and \( v \) components of the Maxwell equations. One finds two constraints

\[ M^{(n)}_v + r^2 f(r) M^{(n)}_r = 0 \Rightarrow (\mathcal{D}_\mu J^\mu = c_1 F \wedge F \,)^{(n-1)} \]

\[ E^{(n)}_{vv} + r^2 f(r) E^{(n)}_{rv} = 0 \Rightarrow (\mathcal{D}_\mu T^\mu_v = F_{\nu \alpha} J^\alpha \,)^{(n-1)} \]

which, as indicated, correspond to the current and energy momentum non-conservation relations at order \( n - 1 \). The combinations \( E_{rr} = 0 \), \( E_{rv} + r^2 f(r) E_{rr} = 0 \) and \( M_r = 0 \) leads respectively to the set of differential equations

\[ 3W^{(n)}_1(\rho) - \frac{3}{2} \rho^{-1} \left( \rho^2 \partial_\rho W^{(n)}_2(\rho) \right)' = S^{(n)}(\rho), \quad (8.24) \]

\[ \left( \rho^4 W^{(n)}_3 \right)' + 8\rho^3 W^{(n)}_1 - \sqrt{2} Q c^{(n)} + (1 - 4\rho^4) W^{(n)}_2 - 4\rho^3 W^{(n)}_2 = K^{(n)}(\rho), \quad (8.25) \]

\[ \left( \rho^3 \partial_\rho c^{(n)} \right)' - 2\sqrt{3} Q W^{(n)}_1 + 3\sqrt{3} Q W^{(n)}_2 = C^{(n)}(\rho). \quad (8.26) \]

At this stage there is still some gauge freedom in the metric. There are three (metric) scalar fields \( (W_1, W_2 \text{ and } W_3) \) but the Einstein’s equations give two differential equations, \( 8.24 \) and \( 8.25 \). We choose the gauge \( W_2(\rho) = 1 \) in which the system partially decouples and can

---

4.1, 3 and 5 denote the \( SO(3) \) scalars, vectors and tensors in which the fields are decomposed.

5. Notice that there are no curvature terms in \( 8.22 \) and \( 8.23 \) because we are working with a flat boundary.
be solved as

\[ W_1^{(n,\varepsilon)}(\rho) = -\frac{1}{3} \int_0^{\rho} \frac{1}{x^3} \, dx S^{(n)}(x), \] (8.27)

\[ c^{(n,\varepsilon)}(\rho) = c_0 \left( \frac{1 - \varepsilon^2 \rho^2}{\rho^2} - \int_0^{\rho} \frac{1}{y^3} \, dy \left( C^{(n)}(y) + \frac{2Q}{\sqrt{3}} S^{(n)}(y) \right) \right), \] (8.28)

\[ W_3^{(n,\varepsilon)}(\rho) = -\frac{2Qc_0}{\sqrt{3}} \left( \frac{1 - \varepsilon^2 \rho^2}{\rho^6} + \frac{1}{\rho^4} \int_0^{\rho} \frac{1}{x^2} \, dx \left( K^{(n)}(x) - 8x^2 W_1^{(n,\varepsilon)}(x) + \frac{2Q}{\sqrt{3}} \partial_\varepsilon c^{(n,\varepsilon)}(x) \right) \right). \] (8.29)

These solutions have been constructed by requiring Dirichlet boundary conditions at the cutoff surface and demanding regularity at the interior of the bulk. The remaining integration constant \( c_0 \) is associated to the freedom of choosing frame in the hydrodynamic set up.

In a similar way, the vector sector is constructed with the components of the equations of motion \( E_{ri}, E_{vi} \) and \( M_i \). They lead to a constraint equation,

\[ E^{(n)}_{vi} + r^2 f(r) E^{(n)}_{ri} = 0 \quad \Rightarrow \quad (D_\mu T^{\mu}_i = F_{i\alpha} J^\alpha)^{(n-1)}, \] (8.30)

implying the energy conservation equation, and the two dynamical equations

\[ \partial_\rho \left( \rho^5 \partial_\rho W_4^{(n)} + 2\sqrt{3} Q a_i^{(n)}(\rho) \right) = J_i^{(n)}(\rho), \] (8.31)

\[ \partial_\rho \left( \rho^3 f(\rho) \partial_\rho a_i^{(n)}(\rho) + 2\sqrt{3} Q \partial_\rho W_4^{(n)}(\rho) \right) = A_i^{(n)}(\rho), \] (8.32)

corresponding to \( E_{ri} = 0 \) and \( M_i = 0 \) respectively. The general solution of this system in the Landau frame has been found in [31]. It is straightforward to generalize the solution to the case in which electromagnetic sources are included. In this case new divergences arise that need to be regulated with the cut-off \( 1/\varepsilon_s \), and then to be substracted with the corresponding counterterms (7.29). The result is

\[ a_\nu^{(2,\varepsilon)} = \frac{1}{2} \left( \frac{1}{\varepsilon_s} A_\nu \left( 1/\varepsilon_s \right) - \int_1^{\rho_s} \, dx A_\nu(x) \right) - \frac{\sqrt{3} Q}{M} C^{(\varepsilon)}_\nu - \frac{\sqrt{3} Q}{4M} D^{(\varepsilon)}_\nu, \] (8.33)

where the integration constant \( C^{(\varepsilon)}_\nu \) is determined by fixing the Landau frame, and \( D^{(\varepsilon)}_\nu \) by demanding regularity at the outer horizon. These constants write

\[ 4C^{(\varepsilon)}_\nu = -\sum_{m=0}^{\infty} \frac{(-1)^m \varepsilon_s^m}{\varepsilon_s^{M+1}(M+1)!} + \int_1^{\rho_s} \, dx A_\nu(x) - \varepsilon_s^{(q)} \log \varepsilon_s, \] (8.34)

\[ D^{(\varepsilon)}_\nu = -\sqrt{3} Q \int_1^{\rho_s} \, dx \frac{A_\nu(x)}{x^2} - M \int_1^{\rho_s} \, dx \frac{A_\nu(x)}{x^4} - Q^2 \int_1^{\rho_s} \, dx \frac{A_\nu(x)}{x^6}. \] (8.35)
Finally the tensor equations are the combination $E_{ij} - \frac{1}{3} \delta_{ij} \text{tr} (E_{kl}) = 0$, which leads to the dynamical equation

$$\partial_\rho \left( \rho^5 f(\rho) \partial_\rho W^{(n)}_{ij}(\rho) \right) = P^{(n)}_{ij}(\rho). \quad (8.36)$$

The solution of this equation that satisfies the Dirichlet boundary and regularity conditions writes

$$W^{(n,\epsilon_*)}_{\mu\nu}(\rho) = - \int^{\frac{1}{\epsilon_*}}_\rho \frac{\int^{\frac{1}{\epsilon_*}}_1 dy P^{(n)}_{\mu\nu}(y)}{x^5 f(x)} \cdot (8.37)$$

After doing an asymptotic expansion of this solution around the regularized boundary surface, one can extract the relevant quantity to get the energy momentum tensor, cf. (8.11),

$$4W^{(4,\epsilon_*)}_{5\mu\nu} = - \sum_{m=0}^{2} \frac{(-1)^m \partial^m \rho P_{\mu\nu}(1/\epsilon_*)}{\epsilon_*^{m+1} (m + 1)!} - \int^{\frac{1}{\epsilon_*}}_1 \text{dx} P_{\mu\nu}(x). \quad (8.38)$$

Note that the form of the homogeneous part in the dynamical equations in the scalar, vector and tensor sectors is the same at any order in the derivative expansion. Each order $n$ is then characterized by the specific form of the sources. In the next two sections we will compute the sources, and integrate them according to the formulae presented above to get the transport coefficients at first and second order.

### 8.2 First Order Transport Coefficients

The technology presented in Sec. 8.1 can be used to construct the solutions of the system at any order in a derivative expansion. As it has been already explained, the solution at zeroth order trivially leads to the charged blackhole with constant parameters (8.6)-(8.7). In this section we will solve the system up to first order. The transport coefficients at this order have been obtained previously in the literature using different methods in field theory and holography. In particular, they have been computed within the fluid/gravity approach, but not including external electric fields in this formalism, see eg. [31, 32, 98].

#### 8.2.1 Scalar sector

In the scalar sector, the first order sources look like

$$S^{(1)}(\rho) = K^{(1)}(\rho) = C^{(1)}(\rho) = 0. \quad (8.39)$$
This very simple situation leads to the solution

\[ W_1^{(1,\varepsilon)}(\rho) = 0, \quad (8.40) \]

\[ c^{(1,\varepsilon)}(\rho) = c_0 \frac{(1 - \varepsilon_+^2 \rho^2)}{\rho^2}, \quad (8.41) \]

\[ W_3^{(1,\varepsilon)}(\rho) = -\frac{2Qc_0 (1 - \varepsilon_+^2 \rho^2)}{\sqrt{3} \rho^6}. \quad (8.42) \]

The integration constant \( c_0 \) can be fixed to zero because it just redefines the fluid charge and energy densities.

### 8.2.2 Vector and tensor sector

The first order sources are given by

\[ J_\mu^{(1)} = \lambda \frac{96}{\rho^3} \left( \frac{5Q^2}{\rho^2} - M \right) B_\mu r_+ + \sqrt{3}Q\lambda \left( \frac{1008Q^2}{\rho^3} - \frac{320M}{\rho^6} \right) \omega_\mu, \quad (8.43) \]

\[ A_\mu^{(1)} = -\frac{2(2\pi)^2T^3}{r_+^2(1+M)M\rho^2}q^{\mu\nu}D_\nu\bar{\mu} + \left( 1 - \frac{9Q^2}{2M^2} \right) \frac{E_\mu}{r_+} + \frac{16\kappa\sqrt{3}Q}{\rho^3} \frac{B_\mu}{r_+} \]

\[ + \frac{48Q^2}{\rho^5} \omega_\mu + \frac{192\lambda}{M\rho^7} \left( \frac{15Q^4M}{4\rho^4} - \frac{4Q^2M^2}{\rho^2} + (1 + 3Q^2M + Q^6) \right) \omega_\mu, \quad (8.44) \]

\[ P_{\mu\nu}^{(1)} = -6r_+\rho^2\sigma_{\mu\nu}, \quad (8.46) \]

where \( D_\mu \) is the Weyl covariant derivative and \( D_\alpha Q = -\frac{2\pi T^2}{\sqrt{3}r_+^2(1+M)} D_\alpha \bar{\mu} \). Using Eqns. (8.10), (8.11), (8.33), (8.34) and (8.35) it is straightforward to find the first order transport coefficients,

\[ \eta = \frac{r_+^3}{4\pi G}, \quad \sigma = \frac{\pi r_+^4 T^2}{16Gm^2}, \quad (8.47) \]

\[ \xi_B = \frac{\sqrt{3}q (m + 3r_+) \kappa}{8Gm\pi r_+^2} - \frac{\sqrt{3}\pi q T^2 \lambda}{Gm}, \quad \xi_V = \frac{3q^2\kappa}{4Gm\pi} - \frac{2\pi (2q^2 - r_+^4) T^2 \lambda}{Gmr_+^2}. \quad (8.48) \]

Chiral magnetic \( \xi_B \) and vortical \( \xi_V \) conductivities have been computed at first order in holography within the Kubo Formulae formalism in [39]. Here we reproduce the same result within the fluid/gravity approach.\(^6\)

Note that to compute the first order transport coefficients one needs only the terms \( a_\mu^{(2,\varepsilon)} \) and \( W^{(4,\varepsilon)} \) in the near boundary expansion. However, in order to go to the next order

\(^6\)The gauge gravitational anomaly contribution to the vortical conductivity was also computed recently within the Fluid/Gravity setup in [98].
in the derivative expansion, we need to know the exact solutions, which can be written in terms of the sources as

\[ W_{\mathbf{4}_\mu}^{(1)}(\rho) = F_1[\rho] P_{\mu}^\nu D_\nu Q(x) + F_2[\rho] \omega_\mu(x) + F_3[\rho] \frac{E_\mu(x)}{r_+} + F_4[\rho] \frac{B_\mu(x)}{r_+}, \]  

\[ W_{\mathbf{5}_{\mu\nu}}^{(1)}(\rho) = F_5[\rho] r_+ \sigma_{\mu\nu}(x), \]  

\[ a_{\mathbf{4}_\mu}^{(1)}(\rho) = F_6[\rho] P_{\mu}^\nu D_\nu Q(x) + F_7[\rho] \omega_\mu(x) + F_8[\rho] \frac{E_\mu(x)}{r_+} + F_9[\rho] \frac{B_\mu(x)}{r_+}, \]  

we show in Appendix H the expressions for the \( F \)'s functions. \( F_5 \) writes

\[ F_5[\rho] = -\frac{2\log[1+\rho]}{-1+M} \frac{(1+\rho_2 + \rho_3^2) \log[\rho - \rho_2]}{(1+\rho_2)(1+2\rho_3^2)} + \frac{2(1+\rho_3^2) \log[\rho + \rho_2]}{-2-2\rho_2^2+4\rho_3^2} + \frac{\log[1+\rho^2 + \rho_3^2]}{2+5\rho_2^2+2\rho_3^2} + \frac{i(1+\rho_3^2)^{3/2} \log[\rho - i\sqrt{1+\rho_2^2}]}{2+5\rho_2^2+2\rho_3^2} - \frac{i(1+\rho_3^2)^{3/2} \log[\rho + i\sqrt{1+\rho_2^2}]}{2+5\rho_2^2+2\rho_3^2}, \]  

\subsection{8.3 Second Order Transport Coefficients}

The second order coefficients are much more computationally demanding than the first order ones. The parameter \( c^{(2,\epsilon_\ast)} \) in (8.10) can always be chosen to be zero, as it just redefines the charge and mass of the black hole. On the other hand, because we are working with a conformal fluid in the Landau frame, there is no contribution from the scalar sector to the energy momentum tensor and \((W_2+W_3)^{(4,\epsilon_\ast)}\) is set to zero. We have checked that this is in fact what happens by using the sources for the scalar sector. So, we will focus in this section on the vector and tensor contributions.

\subsection{8.3.1 Vector sector}

The second order sources in the vector sector are shown in the Appendix I.1, again using these expressions and the Eqs. (8.33), (8.34), (8.35) and (8.10) we can extract the second
order transport coefficients. We show first the new non anomalous coefficients

\[ \xi_5 = f_5(\rho_2), \]  
(8.53)

\[ \xi_6 = f_6(\rho_2) + \frac{3(3+M^2)Q^2\kappa^2}{4\pi GM^3} + \lambda^2 f_7(\rho_2) + \kappa \lambda f_8(\rho_2), \]  
(8.54)

\[ \xi_7 = f_9(\rho_2), \]  
(8.55)

\[ \xi_8 = \frac{(9 + 12M + 7M^2)\pi QT^3}{128\sqrt{3}GM^4(1 + M)r_+^3} + \frac{1}{r_+^3} \left( \kappa^2 f_{11}(\rho_2) + \lambda^2 f_{12}(\rho_2) + \kappa \lambda f_{13}(\rho_2) \right), \]  
(8.56)

\[ \xi_9 = \frac{Q(88 + 480Q^2 + 480Q^4 + 169Q^6)}{512\sqrt{3}GM^4r_+} + \frac{1}{r_+} \left( \kappa^2 f_{14}(\rho_2) + \lambda^2 f_{15}(\rho_2) + \kappa \lambda f_{16}(\rho_2) \right), \]  
(8.57)

\[ \xi_{10} = \frac{(4 + 7Q^2)}{64\pi GM} + \kappa^2 f_{17}(\rho_2) + \lambda^2 f_{18}(\rho_2) + \kappa \lambda f_{19}(\rho_2), \]  
(8.58)

these coefficients are completely new and the rest of the non anomalous where computed in the past but without the gravitational anomaly, the $\hat{\lambda}$ corrected result read as

\[ \xi_1 = \frac{\pi T^3}{8GM^3(M + 1)r_+^3} \left( Q^2 + \frac{M^2}{(1 + 2\rho_2^2)} \log \left[ \frac{2 + \rho_2^2}{2 - \rho_2^2} \right] \right), \]  
(8.59)

\[ \xi_2 = \frac{(3 + M)(3 + M - 6)T^2}{128GM^3(M + 1)r_+^3} + \frac{3\pi Q^2T^3\kappa^2}{GM^3(M + 1)r_+^3} + \frac{1}{r_+^3} \left( \lambda^2 f_1(\rho_2) + \kappa \lambda f_2(\rho_2) \right), \]  
(8.60)

\[ \xi_3 = \frac{3\sqrt{3}Q^3r_+}{64\pi GM^2}, \]  
(8.61)

\[ \xi_4 = \frac{3\sqrt{3}Q^3r_+\kappa^2}{2\pi GM^2} + r_+ \lambda^2 f_3(\rho_2) + r_+ \kappa \lambda f_4(\rho_2), \]  
(8.62)

while the new anomalous coefficients write

\[ \bar{\xi}_2 = -\frac{3\sqrt{3}Q^3(6 + M)\kappa}{16\pi GM^2(1 + 2\rho_2^2)^2} - \frac{\sqrt{3}\pi QT^2\kappa \log \left[ \frac{2 + \rho_2^2}{1 - \rho_2^2} \right]}{2GMr_+^2(1 + 2\rho_2^2)^3} + \lambda \bar{f}_2(\rho_2), \]  
(8.63)

\[ \bar{\xi}_3 = -\frac{\sqrt{3}\pi QT^2}{8r_+^2M^3G} \left( Q^2\kappa + \frac{8\pi^2T^2\lambda}{r_+^2} \right), \]  
(8.64)

\[ \bar{\xi}_4 = \kappa f_3(\rho_2) + \lambda \bar{f}_4(\rho_2), \]  
(8.65)

\[ \bar{\xi}_5 = \kappa \bar{f}_5(\rho_2) + \lambda \bar{f}_6(\rho_2) \]  
(8.66)

and the already known with the $\lambda$ contribution

\[ \bar{\xi}_1 = -\frac{3Q^2r_+\kappa}{4\pi GM^2} + \lambda r_+ \bar{f}_1(\rho_2). \]  
(8.67)
The $f$'s functions are defined in Appendix J. These functions are sometimes complicated, and in these cases we present the result in an expansion at small $\rho_2$ up to order $O(\rho_2^2)$, which is equivalent to order $O(\bar{\mu}^2)$. These coefficients enter in the constitutive relation for the current through (4.95) and (4.90).

### 8.3.2 Tensor sector

The second order sources in the tensor sector are shown in the Appendix I.2 and again after substituting in the equation (8.38) and (8.11) we can extract the transport coefficients at this order. Because of the length of the expression some of them will be shown exactly and the rest are expressed in term of some functions $f_i(\rho_2)$ which are presented in the appendix J. Again we split the result in term of the new non anomalous

\begin{align*}
\lambda_7 &= -\frac{\sqrt{3}(-3+5M)Qr_+}{64\pi GM^2}, \\
\lambda_8 &= r_+f_{22}(\rho_2), \\
\lambda_9 &= f_{23}(\rho_2), \\
\lambda_{10} &= \frac{11}{96\pi G} + \kappa^2 f_{24}(\rho_2) + \kappa \lambda f_{25}(\rho_2) + \lambda^2 f_{26}(\rho_2), \\
\lambda_{11} &= -\frac{8\sqrt{3}Qr_+ \kappa \lambda}{\pi G}, \\
\lambda_{12} &= -\frac{\sqrt{3}Qr_+}{16\pi G} + \frac{3\sqrt{3}Q^3 r_+ \kappa^2}{\pi GM} + \kappa \lambda r_+ f_{27}(\rho_2) + \lambda^2 r_+ f_{28}(\rho_2),
\end{align*}

and the rest

\begin{align*}
\lambda_1 &= \frac{r_+^2}{16\pi G} \left(2 + \frac{M}{\sqrt{4M-3}} \log \left[\frac{3 - \sqrt{4M-3}}{3 + \sqrt{4M-3}}\right]\right), \\
\lambda_2 &= \frac{r_+^2}{8\pi G}, \\
\lambda_3 &= \frac{2r_+^2}{16G\pi} \left(192Q^2 \kappa \lambda - \frac{384(3M-5)\pi T \lambda^2}{r_+} + \frac{M}{1+2\rho_2^2} \log \left[\frac{2+\rho_2^2}{1-\rho_2^2}\right]\right), \\
\lambda_4 &= -\frac{Q^2 r_+^2}{16\pi G} + \frac{3Q^4 r_+^2 \kappa^2}{\pi GM} + \frac{18Q^2 (5+Q^2 (9Q^2-16)) r_+^2 \kappa \lambda}{5\pi GM} + \lambda^2 r_+^2 f_{20}(\rho_2), \\
\lambda_5 &= -\frac{\pi Q T^3}{16\sqrt{3}GM^2 (M+1)r_+}, \\
\lambda_6 &= r_+^2 f_{21}(\rho_2),
\end{align*}
while the new anomalous are

\[
\begin{align*}
\tilde{\lambda}_4 & = \frac{3Q^2 r_+ \kappa}{2\pi GM} + 4\pi T^2 \lambda \frac{\lambda}{GMr_+}, \\
\tilde{\lambda}_5 & = \kappa r_+ f_8(\rho_2) + \lambda r_+ f_9(\rho_2), \\
\tilde{\lambda}_6 & = \kappa f_{10}(\rho_2) + \lambda f_{11}(\rho_2), \\
\tilde{\lambda}_7 & = \frac{2r_+ \lambda}{G\pi}, \\
\tilde{\lambda}_8 & = -\frac{3Q^2 (Q^2 - 1) r_+ \kappa}{4\pi GM^2} + \lambda r_+ f_{12}(\rho_2)
\end{align*}
\]

and the rest

\[
\begin{align*}
\tilde{\lambda}_1 & = \frac{\sqrt{3}Q^2 r_+^2 \kappa}{4\pi GM} + \left( -\frac{\sqrt{3}Q^2 r_+}{\pi G} + \frac{2\sqrt{3}\pi QT^2}{GM} \right) \lambda, \\
\tilde{\lambda}_2 & = \lambda r_+ f_7(\rho_2), \\
\tilde{\lambda}_3 & = -\frac{2T^2 \lambda}{G(M + 1)}.
\end{align*}
\]

These coefficients enter in the constitutive relation for the energy momentum tensor through \((4.95)\) and \((4.89)\).

The transport coefficients \(\lambda_1, \ldots, \lambda_6, \tilde{\lambda}_1, \ldots, \tilde{\lambda}_3\) and \(\xi_1 \ldots \xi_4, \tilde{\xi}_1\) where computed in the past in \([31, 32]\) without gravitational anomaly. It is interesting to remark that \(\tilde{\lambda}_1, \lambda_2, \lambda_5, \lambda_6, \xi_1\) and \(\xi_3\) do not receive \(\lambda\)–corrections, actually these coefficients also do not depend on \(\kappa\). It is also remarkable that \(\tilde{\lambda}_2\) and \(\tilde{\lambda}_3\) in the presence of gravitational anomaly are not vanishing. The rest of the transport coefficients computed are new.

It is also interesting to compare our results with the predictions done in \([60]\), basically the authors tried to fix the anomalous second order transport coefficients using a generalized version of the method developed by Son & Surowka \([33]\). The only issue is that they didn’t consider the mixed gauge-gravitational anomaly and neglected all the integration constants as the last authors. At present days we know that at least at first order these integration constants might be related with the anomalous parameter \(\lambda\). The authors presented a set of algebraic and differential constraints. The algebraic one is

\[
\begin{align*}
\tilde{\lambda}_4 & = \frac{2\eta}{n} (\xi_V - 2TD_B), \\
\tilde{\lambda}_4 & = \frac{2\eta}{n} (\xi_B - \kappa\mu), \\
\tilde{\xi}_3 & = \frac{\sigma}{n} (\xi_V - 2TD_B), \\
\tilde{\xi}_5 & = 0,
\end{align*}
\]
where $D_B = \frac{k}{8\pi G_\Lambda^2} \bar{\mu}^2$ is the coefficient multiplying the magnetic field in the entropy current computed in \cite{33, 34, 60} with only pure gauge anomaly and $\kappa = \frac{k}{2\pi G_\Lambda}$ is the anomalous parameter used by the authors of \cite{60}. The Eqs. (8.88) and (8.90) are satisfied by our solutions (8.85) and (8.64) in the $\lambda = 0$ case. However the equation (8.89) is satisfied with the gravitational anomaly switched on. So far, these constraints are satisfied except the Eq. (8.91), $\tilde{\xi}_5$ is not vanishing in our model even though we fix the $\lambda-$parameter to vanish.

In fact it is possible to write a Kubo formula for $\tilde{\xi}_5$, this formula will relate two point functions at second order in a frequency and momentum expansion with it. Actually it will appear in the same correlator as the chiral magnetic conductivity. To do so let us switch on a gauge field in the $y$ direction $A_y = A_y(t,z)$, in such a situation the Fourier transformed source $J_{(5)}^{\mu}$ is reduced to

$$J_{(5)}^{\mu} = \omega k_z A_y, \quad (8.92)$$

so using the constitutive relation we can read the two point function

$$\langle \partial^x \partial^y \rangle = -i \tilde{\xi}_5 \delta_{5} k_z + \tilde{\xi}_5 \omega k_z. \quad (8.93)$$

The presence of $\tilde{\xi}_5$ must be captured by a model in the probe limit. The very simple model of the Chapter 5 is enough to be used as a consistency check. In order to proceed we will work only with an axial gauge field switched on, so we just need to solve the equations (5.20) and follow the standard holographic procedure describe in previous chapters in order to obtain the retarded correlator, the final result is

$$\langle \partial^a \partial^b \rangle = \left( \begin{array}{cc}
-\frac{\omega}{\epsilon} + \frac{\omega^2 \log^2 2}{4\epsilon} - 72g \kappa \mu^2 (-1 + \log 4) & -\kappa \mu \log 2 - 12i k \kappa \mu + 12k \omega \kappa \mu \log 2 \\
12i k \kappa \mu - 12k \omega \kappa \mu \log 2 & -\frac{\omega}{\epsilon} + \frac{\omega^2 \log^2 2}{4\epsilon} - 72(k \kappa \mu)^2 g A (-1 + \log 4) \end{array} \right). \quad (8.94)$$

In order to relate the Fluid/Gravity model with the one in Chapter 5 we have to do the redefinitions

$$\kappa \rightarrow 24\pi G \kappa, \quad r_+ \rightarrow 1$$

$$g_\Lambda^2 \rightarrow 16\pi G \quad \text{and} \quad T \rightarrow \frac{1}{\pi}.$$  

Finally we will compare from (8.66) the $\kappa-$part because the correlator was computed in the probed limit where the backreaction of the gauge field on the background black hole is neglected and in consequence the effect of the gravitational anomaly is subleading. After doing a linear expansion for $\bar{\mu} \ll 1$ we get

$$\tilde{\xi}_5 = 12 \kappa \mu \log 2 - \frac{\lambda \mu}{\pi G r_+} (1 + 2 \log 2) + O(\bar{\mu}^3). \quad (8.95)$$

This is a non trivial check of the non vanishing of $\tilde{\xi}_5$, in order to understand the discrepency between this result and the prediction done by the authors of \cite{60}, we can analyse the
properties under time reversal of the source associated to $\tilde{\xi}_5$ which reads in the constitutive relations as

$$J^\mu = \tilde{\xi}_5 e^{\mu\nu\rho\lambda} u_\nu D_\rho E_\lambda + \ldots$$  \hspace{1cm} (8.96)

this equation in the local rest frame $u^\mu = (1, 0, 0, 0)$ looks like

$$\vec{J} = \xi_5 \nabla \times \vec{E} + \ldots = -\xi_5 \frac{\partial \vec{B}}{\partial t} + \ldots,$$  \hspace{1cm} (8.97)

but the electric field and the operator $\nabla \times$ are even under time reversal and the current is odd, in consequence the conductivity $\tilde{\xi}_5$ is $\mathcal{T}$–odd. The fact of this transport coefficient been $\mathcal{T}$–odd is telling us that such a source must contribute to the entropy production and demanding a non vanishing contribution to the production of entropy only can take us to a trivial result, the same would happen if we demand of the normal electric conductivity a vanishing contribution. We also can see the odd property of $\tilde{\xi}_5$ from Eq. (8.93) because $\langle J^x J^y \rangle$ is $\mathcal{T}$–even and inverting the time is the same as changing $\omega \rightarrow -\omega$. A last interesting observation comes from the result on the dispersion relation of shear waves in [60], where they have found that

$$\omega \approx -i \frac{\eta}{4p} k^2 \mp iCk^3 + \ldots$$  \hspace{1cm} (8.98)

with $C = \frac{\lambda_1}{16p}$, so it would be interesting to generalize the computation of [103] to the case including the mixed gauge-gravitational anomaly to verify whether the result for $C$ is

$$C = \frac{Q}{Mr_+^2} \left[ \frac{\sqrt{3} \kappa}{4M} - \sqrt{3} \left( 1 - \frac{2\pi^2 T^2}{r_+^2 M} \right) \lambda \right].$$  \hspace{1cm} (8.99)
In the presence of external sources for the energy momentum tensor and the currents, the anomaly is responsible for a non conservation of the latter. This is conveniently expressed through

$$D_\mu j^\mu_a = \varepsilon^{\mu\nu\rho\lambda} \left( \frac{d_{abc}}{32\pi^2} F_{\mu\nu} F_{\rho\lambda} + \frac{b_a}{768\pi^2} \beta_{\mu\nu} \beta_{\rho\lambda} \right), \quad (9.1)$$

where the axial and mixed gauge-gravitational anomaly coefficients, $d_{abc}$ and $b_a$, are given by (2.23) and (2.24) respectively.

We have discussed in Chap. [3] the subtleties of introducing a chemical potential for anomalous charges. One possible way is by deforming the Hamiltonian according to $H \rightarrow H - \mu Q$, a second, usually equivalent way is by imposing boundary conditions $\phi(t-i\beta) = \pm e^{iH\beta} \phi(t)$ on the fields along the imaginary time direction [75, 104]. These methods are equivalent as long as $Q$ is a non-anomalous charge. We have argued why the second method could be physically favoured to be the right formalism. Similarly, in holography we can introduce the chemical potential either through a boundary value of the temporal component of the gauge field or through the potential difference between boundary and horizon. Thus, for non-anomalous symmetries, the boundary value of the temporal gauge field can be identified with the chemical potential. Due to the exact gauge invariance of the action, a constant boundary value never enters in correlation functions. In the presence of a Chern-Simons term, however, the gauge symmetry is partially lost and even a constant boundary gauge field becomes observable. This can be seen explicitly from the three-point functions (5.35) and (5.37). Therefore, we should set the axial vector field to zero after having used it as a source for axial current. By defining the corresponding chemical potential as the potential difference between the horizon of the AdS black hole and the holographic boundary we are able to do so. However, the prize we have to pay is a space time with a special topology at the horizon, this puncture in the bulk behave like a flux and allow us to have the twisted bound-
ary conditions for the fields and makes this approach the holographic dual of the formalism B (see table [3.1]).

We also derived the Kubo formulae that allow the calculation of all the transport coefficients at first order in the hydrodynamic expansion.

Then we computed two- and three-point functions of currents in Chap. 5 at finite density using holographic methods for a simple holographic model incorporating the axial anomaly of the standard model. We were able to reproduce the known weak-coupling results concerning the chiral magnetic effect and also found a new type of “conductivity” in the axial sector alone, \( \sigma_{55} \). Although it can not be probed by switching on external fields, as a two-point function it is as well defined as \( \sigma_{\text{CME}} \). It would be interesting to find a way of also relating this anomalous conductivity to experimentally accessible observables.

Previous calculations of anomalous conductivities have been able to reproduce the weak-coupling result for \( \sigma_{\text{axial}} \propto \mu \) but not \( \sigma_{\text{CME}} \propto \mu^5 \) unless the contributions from the Chern-Simons term to the chiral currents were dropped. In our calculation we have used the complete expressions for the currents, but of key importance was a clear distinction between the physical state variable, the chemical potential, and the external background field. The latter we viewed exclusively as a source that couples to an operator, whereas the chemical potential should correspond in the most elementary way to the cost of energy for adding a unit of charge to the system.

We have confirmed our intuition on the way of introducing anomalous chemical potentials with the computation of three point functions in vacuum and getting the same result as in the holographic model.

Having the Kubo formulae we have computed the magnetic and vortical conductivity at weak coupling and we find contributions that are proportional to the anomaly coefficients (2.23) and (2.24). Therefore the non-vanishing value has to be attributed to the presence of chiral and gravitational anomalies.

This result agrees with the known results from AdS/CFT [36] up to one important difference: the holographic calculation did not show a contribution proportional to \( \text{tr} (T_A) \). This not surprising since only a holographic gauge Chern-Simons term was included. Holographic modelling of the gravitational anomaly called however also for inclusion of a mixed gauge-gravitational Chern-Simons term of the form \( A \wedge R \wedge R \).

We find a non-vanishing vortical conductivity proportional to \( \sim T^2 \) even in an uncharged fluid. In [34] similar terms in the vortical conductivities have been argued for as undetermined integration constant without any relation to the gravitational anomaly. The \( T^2 \) behavior had appeared already previously in neutrino physics [38].

In order to perform the analysis at strong coupling via AdS/CFT methods, we have defined in Chap. 7 a holographic model implementing both type of anomalies via gauge and mixed gauge-gravitational Chern-Simons terms. We have computed the anomalous magnetic and vortical conductivities from a charged black hole background and have found a non-vanishing vortical conductivity proportional to \( \sim T^2 \). These terms are characteristic for the
contribution of the gravitational anomaly and they even appear in an uncharged fluid. Very recently a generalization of the results \((7.60)-(7.62)\) to any even space-time dimension as a polynomial in \(\mu\) and \(T\) \([42]\) has been proposed. Finally, the consequences of this anomaly in hydrodynamics have been studied using a group theoretic approach, which seems to suggest that their effects could be present even at \(T = 0\) \([105]\).

To have a consistent hydrodynamics description of the anomalous holographic plasma we went to second order in the derivative expansion using the Fluid/Gravity correspondence and we computed all the transport coefficients, except the ones associated to the presence of curvature in the fluid background. Within the most important results we have gotten that gravitational anomaly has a non trivial contribution to most of the transport coefficients, even thought to the non anomalous one. In the anomalous side we have found a dissipative conductivity

\[
\tilde{J} = \tilde{\xi} \tilde{\sigma} \nabla \times \tilde{E},
\]

that was though to be vanish for any anomalous model \([60]\), but we have checked our result also using Kubo formulae as a consistency check. The existence of an anomalous dissipative conductivity results counter-intuitive and need to be understood better. We also have found the expression for \(\tilde{\lambda}_1\) in presence of the mixed gauge-gravitational anomaly, which in principle determine the coefficient in front of \(k^3\) in the chiral dispersion relation of shear waves \([60]\).

There are important phenomenological consequencies of the present study to heavy ion physics. In \([16]\) enhanced production of high spin hadrons (especially \(\Omega^-\) baryons) perpendicular to the reaction plane in heavy ion collisions has been proposed as an observational signature for the chiral separation effect. Three sources of chiral separation have been identified: the anomaly in vacuum, the magnetic and the vortical conductivities of the axial current \(J^\mu_A\). Of these the contribution of the vortical effect was judged to be subleading by a relative factor of \(10^{-4}\). The \(T^2\) term in \((7.61)\) leads however to a significant enhancement. If we take \(\mu\) to be the baryon chemical potential \(\mu \approx 10\) MeV, neglect \(\mu_A\) as in \([16]\) and take a typical RHIC temperature of \(T = 350\) MeV, we see that the temperature enhances the axial chiral vortical conductivity by a factor of the order of \(10^4\). We expect the enhancement at the LHC to be even higher due to the higher temperature.

Beyond applications to heavy ion collisions leading to charge and chiral separation effects \([106]\) it is tempting to speculate that the new terms in the chiral vortical conductivity might play a role in the early universe. Indeed it has been suggested before that the gravitational anomaly might give rise to Lepton number generation, e.g. in \([107]\). The lepton number separation due to the gravitational anomaly could contribute to generate regions with non-vanishing lepton number.
En presencia de fuentes externas para el tensor de energía momento y las corrientes, las anomalías son responsables de la no conservación de dicha corriente. Esto se expresa de la siguiente forma \[56\]

$$D_\mu J^\mu_a = \varepsilon_{\mu\nu\rho\lambda} \left( \frac{d_{a\mu\nu}}{32\pi^2} F_{\mu\nu}^b F_{\rho\lambda}^c + \frac{b_a}{768\pi^2} R_\alpha^\alpha R^\beta_{\mu\nu} R^\beta_{\rho\lambda} \right), \tag{10.1}$$

donde los coeficientes axial y el mixto gauge-gravitacional, \(d_{a\mu\nu}\) y \(b_a\), están dados por \(2.23\) y \(2.24\) respectivamente.

En el capítulo 3 hemos discutido las sutilezas de introducir un potencial químico para cargas anómalas. Una posibilidad es deformando el Hamiltoniano según \(H \rightarrow H - \mu Q\), una segunda forma usualmente equivalente es imponiendo las condiciones de frontera \(\phi(t - i\beta) = \pm e^{i\mu\beta} \phi(t)\) sobre los campos a lo largo del eje imaginario del tiempo \(75, 104\). Ambos métodos son equivalentes siempre y cuando \(Q\) no sea una carga anómala. Hemos dado argumentos físicos de por qué el segundo método debería ser el apropiado. Similarmente, en holografía hemos introducido los potenciales químicos a través del valor que toma en la frontera el campo gauge o como la diferencia de potencial entre el horizonte de eventos y la frontera del espacio tiempo. Para simetrías no anómalas el potencial químico puede ser idetificado con el valor del campo gauge en la frontera. Debido a la invariancia gauge de la acción los correladores nunca dependerán del valor en la frontera del campo. Sin embargo, en presencia de un término de Chern-Simons la simetría gauge se pierde parcialmente e inclusive configuraciones constantes en la frontera contribuirán a los correladores y se volverán observables. Esto se ve explícitamente de las funciones a tres puntos \(5.35\) y \(5.37\). Por lo tanto, deberíamos poner a cero el campo axial luego de haberlo usado como una fuente para calcular la función de partición. Al definir el potencial químico como la diferencia de potencial entre el horizonte y la frontera, podemos darle la interpretación de energía necesaria para introducir una unidad de carga en el sistema.
En esta tesis también derivamos la fórmulas de Kubo que permiten el cálculo de todos los coeficientes de transporte a primer orden en la expansión hidrodinámica.

Luego calculamos funciones a dos y tres puntos en el capítulo 5 utilizando métodos holográficos para un modelo simple que incorpora la anomalía axial del modelo standard. En este modelo fuimos capaces de reproducir el resultado conocido del régimen de acoplamiento débil para la conductividad quiral magnética.

Los cálculos previos de conductividades anómalas fueron capaces de reproducir el resultado de acoplamiento débil para $\sigma_{\text{axial}} \propto \mu$ pero no para $\sigma_{\text{CME}} \propto \mu^5$ al menos que la contribución del término de Chern-Simons se eliminara. En nuestro cálculo hemos utilizado la corriente consistente completa. De gran importancia fue la distinción entre potencial químico y el valor asintótico del campo gauge.

Nuestra intuición sobre como introducir el potencial químico fue confirmada por el cálculo de funciones a tres puntos a acoplamiento débil y temperatura cero. Este resultado es una verificación no trivial de que nuestro razonamiento es correcto.

Teniendo conocimiento de las fórmulas de Kubo las utilizamos para calcular las conductividades por campos magnéticos y por vorticidad en un régimen de acoplamiento débil y obtuvimos resultados proporcionales a los coeficientes anómalos (2.23) y (2.24). Por lo tanto estas conductividades son distintas de cero si y solo la teoría presenta anomalías.

Este resultado coincide con el cálculo en AdS/CFT de [36] salvo por una diferencia importante: el cálculo holográfico no mostró la contribución proporcional a $\text{tr}(T_A)$. Pero esto no es una sorpresa porque holográficamente solo la anomalía gauge se reproduciría en este modelo. Para incluir la anomalía gravitacional es necesario incluir en la acción de gravedad un término con la forma $A \wedge R \wedge R$.

Para realizar un análisis completo a acoplamiento fuerte de estas conductividades definimos un modelo en el contexto de AdS/CFT en el capítulo 7 en el cual implementamos ambas anomalías. En este modelo calculamos todas las conductividades usando fórmulas de Kubo y encontramos en la conductividad por vorticidad el término proporcional a $\sim T^2$. Este término está presente si y solo si la anomalía gravitacional está en la teoría al igual que en el caso de acoplamiento débil.

Para finalizar y tener una descripción hidrodinámica consistente de este tipo de sistemas utilizamos la correspondencia fluido/gravedad que permite calcular los coeficientientes de transporte a segundo orden en la expansión derivativa. Utilizando esta técnica fuimos capaces de calcular todos los coeficientes de transporte excepto los asociados a la presencia de curvatura en el medio. Dentro de los resultados más importantes tenemos que inclusive a este orden la anomalía gravitacional presenta contribuciones no triviales. En particular descubrimos una nueva conductividad anómala disipativa asociada a la variación en el tiempo del campo magnético

$$\vec{J} = -\xi_5 \frac{\partial \vec{B}}{\partial t}. \quad (10.2)$$

También encontramos la contribución de $\lambda$ a $\hat{\lambda}_1$, este coeficiente de transporte en principio
determina la contribución $k^3$ en la relación de dispersión quiral de las conocidas *shear waves* [60].

Este trabajo tiene consecuencias fenomenológicas importantes para el estudio de la física de colisiones de iones pesados. En [16] se predijo la producción de hadrones de alto espín (especialmente bariones $\Omega^-$). Esta producción es una consecuencia del efecto de separación de quiralidad. La anomalía gravitacional contribuye importantemente en este efecto porque su aporte va como $T^2$. Así que a temperaturas obtenidas en el LHC quizás sería posible observar este efecto.

Mas allá de la aplicación a la física de colisiones de iones pesados el efecto por separación de quiralidad [106] es un candidato para especular sobre la generación de número leptónico en el universo temprano.
Resumen y Perspectivas
Appendices
We wish to compute the integral corresponding to the triangle diagram in Fig. 6.1,
\[
\Gamma^\mu\nu\rho(p, q) = (-1)(ie)^2(ig)^3 \int \frac{d^d l}{(2\pi)^d} \text{tr} \left( \frac{l - p}{(l - p)^2} \gamma^\mu \frac{l + q}{(l + q)^2} \gamma^\rho \right) 
\]
\[+ (\mu \leftrightarrow \nu, p \leftrightarrow q). \quad (A.1)\]

Using Feynman parametrization the integral can be written as
\[
\Gamma^\mu\nu\rho(p, q) = I_{\alpha\beta\gamma} \left[ \text{tr} \left( \gamma^\alpha \gamma^\nu \gamma^\beta \gamma^\gamma \gamma^\rho \right) - \text{tr} \left( \gamma^\gamma \gamma^\nu \gamma^\beta \gamma^\alpha \gamma^\rho \right) \right], \quad (A.2)
\]
\[I_{\alpha\beta\gamma} = -2 \int_0^1 dx dy \Theta(1 - x - y) \int \frac{d^d l}{(2\pi)^d} \frac{N_{\alpha\beta\gamma}}{(l^2 + D)^3}, \quad (A.3)\]
where
\[
D = x(1 - x)p^2 + 2xyp \cdot q + y(1 - y)q^2, \quad (A.4)
\]
\[r_\mu = xp_\mu - yq_\mu, \quad (A.5)\]
\[N_{\alpha\beta\gamma} = (r - p)_\alpha r_\beta (r + q)_\gamma + \frac{l^2}{d} \left[ \delta_{\alpha\beta}(r + q)_\gamma + \delta_{\alpha\gamma} r_\beta + \delta_{\beta\gamma}(r - p)_\alpha \right]. \quad (A.6)\]

Here we have already taken into account that with both dimensional and cutoff regularizations, the integral with odd powers of $l$ in the numerator of the integrand vanishes, and the remaining tensor structure is dictated by the rotational symmetry of a momentum shell at fixed $|l|$. Using
\[
\int_0^\Lambda \frac{l^3 dl}{(l^2 + D)^3} = \frac{1}{4D} + O \left( \frac{1}{\Lambda^2} \right), \quad (A.7)
\]
\[\int_0^\Lambda \frac{l^5 dl}{(l^2 + D)^3} = \frac{1}{2} \left[ \log \left( \frac{\Lambda^2}{D} \right) - \frac{3}{2} \right] + O \left( \frac{1}{\Lambda^2} \right), \quad (A.8)\]
in the cutoff regularization \((d = 4,\) and
\[
\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon \int \frac{d^{4-2\epsilon} l}{(2\pi)^{4-2\epsilon} (l^2 + D)^3} \frac{1}{l^2} = \frac{\Gamma(\epsilon)}{16\pi^2} (e^{\gamma_E} \mu^2)^\epsilon \frac{1}{2 D^{1+\epsilon}}, \tag{A.9}
\]
\[
\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon \int d^{4-2\epsilon} l \frac{1}{(2\pi)^{4-2\epsilon} (l^2 + D)^3} = \frac{\Gamma(\epsilon)}{16\pi^2} (e^{\gamma_E} \mu^2)^\epsilon \left(1 - \frac{\epsilon}{2}\right) \frac{1}{D^\epsilon}, \tag{A.10}
\]

in the dimensional regularization \((d = 4 - 2\epsilon)\) with \(\overline{\text{MS}}\) scheme, we find
\[
\Gamma_{\text{reg}}^{\mu\nu\rho}(p, q) = \frac{i}{2\pi^2} \int_0^1 dx dz \Theta(1-x-z) \left[ (A_{\text{reg}}^\mu p_\alpha + B_{\text{reg}}^\mu q_\alpha) e^{\alpha\mu\nu\rho} + (C_{\text{reg}}^{\epsilon\mu} p_\mu + D_{\text{reg}}^{\epsilon\nu} q_\nu) e^{\alpha\beta\nu\rho} + (C_{\text{reg}}^{\epsilon\rho} p_\rho + D_{\text{reg}}^{\epsilon\mu} q_\mu) e^{\alpha\beta\mu\rho} \right], \tag{A.11}
\]

with \(\text{reg} \in \{\text{CO, DR}\}\). The coefficients are given by
\[
A_{\text{CO}} = \frac{(x - 1)r^2 + yq^2}{D} + \left[ \log \left(\frac{\Lambda^2}{D}\right) - \frac{3}{2} \right] (3x - 1), \tag{A.12}
\]
\[
B_{\text{CO}} = \frac{(1 - y)r^2 - xp^2}{D} + \left[ \log \left(\frac{\Lambda^2}{D}\right) - \frac{3}{2} \right] (1 - 3y), \tag{A.13}
\]
\[
C_{1\text{CO}} = \frac{2x(x - 1)}{D}, \tag{A.14}
\]
\[
C_{2\text{CO}} = \frac{2xy}{D}, \tag{A.15}
\]
\[
D_{1\text{CO}} = \frac{-2xy}{D}, \tag{A.16}
\]
\[
D_{2\text{CO}} = \frac{2y(1 - y)}{D}, \tag{A.17}
\]
in the cutoff regularization, and
\[
A_{\text{DR}} = \left[ \frac{(x - 1)(r^2 - D) + yq^2}{D} + (3x - 1) \right] \frac{\Gamma(\epsilon)}{D^{1+\epsilon}} \left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon, \tag{A.18}
\]
\[
B_{\text{DR}} = \left[ \frac{(1 - y)(r^2 - D) - xp^2}{D} + (1 - 3y) \right] \frac{\Gamma(\epsilon)}{D^{1+\epsilon}} \left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon, \tag{A.19}
\]
\[
C_{1\text{DR}} = \frac{2\varepsilon x(x - 1)}{D^{1+\epsilon}} \frac{\Gamma(\epsilon)}{\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon}, \tag{A.20}
\]
\[
C_{2\text{DR}} = \frac{2\varepsilon xy}{D^{1+\epsilon}} \frac{\Gamma(\epsilon)}{\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon}, \tag{A.21}
\]
\[
D_{1\text{DR}} = -\frac{2\varepsilon xy}{D^{1+\epsilon}} \frac{\Gamma(\epsilon)}{\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon}, \tag{A.22}
\]
\[
D_{2\text{DR}} = -\frac{2\varepsilon y(1 - y)}{D^{1+\epsilon}} \frac{\Gamma(\epsilon)}{\left(\frac{e^{\gamma_E} \mu^2}{4\pi}\right)^\epsilon}, \tag{A.23}
\]
in the dimensional regularization.
APPENDIX B

CODAZZI FORM OF EQUATIONS OF MOTION

B.1 Codazzi form of Equations of Motion

We project the equations of motion (7.12) and (7.13) into the boundary surface and the orthogonal direction and rewrite them in terms of quantities at the regulated boundary. Doing so we get a set of two dynamical equations

\[ 0 = \dot{E}^i + KE^i + D_j \dot{F}^{ji} - 4\epsilon^{ijkl} \left( \kappa E_j \dot{F}^{kl} + 4\lambda \dot{K}^s_j D_s K^s_k + 2\lambda \dot{R}^s_{ijkl} D_s K^s_j \right) \]

\[ + 4\lambda K_{ks} K^s_i D_s K^s_j + 4\lambda K_{ks} K^s_i D_s K^s_k \] (B.1)

\[ 0 = \dot{K}^j + K_K^j - \dot{R}^j + \frac{1}{2} E^i E_j + \frac{1}{2} \dot{F}^{lm} \dot{F}_{jm} - \frac{\delta^j_i}{(d-1)} \left( 2\Lambda + \frac{1}{2} E^m E_m + \frac{1}{4} \dot{F}^{lm} \dot{F}_{lm} \right) \]

\[ + 2\lambda \left[ -2\epsilon^{ijkl} \partial_r (\dot{F}_{kl} K^r_{mj}) + 2\epsilon^{ijklm} \partial_r (\dot{F}_{kl} K^r_{ms} K^s_{jm}) + 2\epsilon^{ijklm} \partial_r (E_k D_m K^s_{jl}) \right. \]

\[ - \epsilon^{klmn} \dot{F}_{kl} \left( K^s_{ij} K^s_{mn} + 2K^s_{im} K^s_{nj} - 2K^s_{ij} K^s_{nm} \right) + 4\epsilon^{ijklm} \partial_r (E_k D_m K^s_{jl}) \]

\[ + 2\epsilon^{ijklm} D_s (\dot{F}_{kl} (D_j K^s_m - D^s K^s_{jm})) + 4\epsilon^{ijklm} E_k K^s_{ij} D_l K^s_m \]

\[ - 4\epsilon^{klmn} E_k K^s_{ij} D_n K^s_{mj} + 2\epsilon^{ijklm} D_s (E_k (\dot{R}^s_{ij} l_m - 2K^s_{ij} K_{jm})) \right] , \quad (B.2) \]
and three constraints

\[ 0 = K^2 - K_{ij}K^{ij} - \hat{R} - 2\Lambda - \frac{1}{2}E_iE^i + \frac{1}{4}\hat{F}_{ij}\hat{F}^{ij} \]

\[ + 8\lambda \varepsilon^{ijkl}(D_m(\hat{F}_{ij}D_kK^m_l) + \hat{F}_{ij}K_{km}\dot{K}^m_l + 2E_iK_{ji}D_jK^i_k), \] (B.3)

\[ 0 = D_jK^{ji} - D^jK + \frac{1}{2}E_j\hat{F}^{ji} + 2\lambda \varepsilon^{klmi}D_j[2E_kD_lK^l_j + \hat{F}_{kl}(K^l_m + K^l_jK^m_s)] \]

\[ + \lambda \varepsilon^{klmn}\{2\hat{F}_{kl}K^l_mD_mK^m_n + D_j[\hat{F}_{kl}(\hat{R}^{ij}nm + 2K^l_mK^m_n)] \]

\[ + 2E_kK^l_m\hat{R}^i_{jnl} + 2\hat{F}_{kl}K^l_m(D^l_jK_nj - D_jK^l_n) + 2\partial_r(\hat{F}_{kl}D_nK^i_m)\}, \] (B.4)

\[ 0 = D_iE^i - \varepsilon^{ijkl}(\kappa\hat{F}_{ij}\hat{F}_{kl} + \lambda \hat{R}^i_{tiij}\hat{R}^i_{skl} + 4\lambda K_{is}K^j_{jk}\hat{R}^i_{tskl} + 8\lambda D_iK_{sj}D_jK^s_k), \] (B.5)

with the notation

\[ X^{(i)}_{(j)} := \frac{1}{2}(X^i_{(j)} + X^j_{(i)}), \quad X^{[i]}_{[j]} := \frac{1}{2}(X^i_{[j]} - X^j_{[i]}). \] (B.6)

We take Eq. (B.6) as a definition, and it should be applied also when \( X \) includes derivatives on \( r \), for instance \( X^{(i)}\hat{K}_{lj} = \frac{1}{2}(X^i\hat{K}_{lj} + X^j\hat{K}_{il}). \)
APPENDIX C

TECHNICAL DETAILS ON HOLOGRAPHIC RENORMALIZATION

C.1 Technical details on Holographic Renormalization

The renormalization procedure follows from an expansion of the four dimensional quantities in eigenfunctions of the dilatation operator

\[ \delta_D = 2 \int d^4x \gamma_{ij} \frac{\delta}{\delta \gamma_{ij}}. \] (C.1)

This expansion reads

\[ K^i_j = K^i_j(0) + K^i_j(2) + K^i_j(4) \log e^{-2r} + \cdots, \] (C.2)
\[ A_i = A_i(0) + A_i(2) + A_i(4) \log e^{-2r} + \cdots, \] (C.3)

where

\[ \delta_D K^i_j(0)_j = 0, \quad \delta_D K^i_j(2) = -2K^i_j(2), \]
\[ \delta_D K^i_j(4) = -4K^i_j(4) - 2\tilde{K}^i_j(4), \quad \delta_D \tilde{K}^i_j(4) = -4\tilde{K}^i_j(4), \]
\[ \delta_D A_i(0)_i = 0, \quad \delta_D A_i(2) = -2A_i(2) - 2\tilde{A}_i(2), \]
\[ \delta_D \tilde{A}_i(2) = -2\tilde{A}_i(2). \] (C.4)

Given the above expansion of the fields one has to solve the equations of motion in its Codazzi form, order by order in a recursive way. To do so one needs to identify the leading order in dilatation eigenvalues at which each term contributes. One has

\[ \gamma_{ij} \sim O(-2), \quad \gamma^i_j \sim O(2), \quad E_i \sim O(2), \quad \tilde{F}_{ij} \sim O(0), \]
\[ \sqrt{-\gamma} \sim O(-4), \quad K^i_j \sim O(0), \quad \tilde{R}^i_{jkl} \sim O(0), \quad \nabla_i \sim O(0). \] (C.5)
Note that for convenience of notation we define $\mathcal{O}(n)$ if the leading eigenvalue of the di-
latation operator is $-n$. In practice, in the renormalization procedure one needs to use the 
equations of motion Eqs. (B.2) and (B.3) up to $\mathcal{O}(2)$ and $\mathcal{O}(4) + \mathcal{O}(\tilde{4})$ respectively. Up to $\mathcal{O}(0)$ they write

$$0 = K_{(0)}^2 - K_{(0)}^i K_{(0)}^i - 2\Lambda, \quad (C.6)$$

$$0 = K_{(0)}^i + K_{(0)} K_{(0)}^j - \frac{2\Lambda}{(d-1)} \delta^i_j. \quad (C.7)$$

Order $\mathcal{O}(2)$ writes

$$0 = 2K_{(0)} K_{(2)}^i - 2K_{(0)}^i K_{(2)}^j - \dot{\hat{K}}_i, \quad (C.8)$$

$$0 = K_{(2)}^i |_{(2)} + K_{(0)} K_{(2)}^j + K_{(2)}^i K_{(2)}^j - \dot{\hat{K}}_i, \quad (C.9)$$

and finally orders $\mathcal{O}(4)$ and $\mathcal{O}(\tilde{4})$ for Eq. (B.3) write respectively

$$0 = 2K_{(0)} K_{(4)} + K_{(2)}^2 - 2K_{(0)}^i K_{(4)}^j - K_{(2)}^i K_{(2)}^j + \Lambda\dot{\hat{P}}_0 i j \delta^i_j, \quad (C.10)$$

$$0 = 2 \left( K_{(0)} K_{(4)} - K_{(0)}^i K_{(4)}^j \right) \log e^{-2r}. \quad (C.11)$$

The derivative on $r$ can be computed by using

$$\frac{d}{dr} = \int d^4x K_{(0)}^l \frac{\delta}{\delta \gamma_{km}} = 2 \int d^4x K_{(0)}^l \frac{\delta}{\delta \gamma_{km}}. \quad (C.12)$$

By inserting in this equation the expansion of $K_{(0)}^l$ given by Eq. (C.2), one gets $d/dr \simeq \delta_D$ at the lowest order. Taking into account this, the computation of $K_{(0)}^l$ is trivial if one considers the definition of $K_{ij}$, i.e.

$$K_{(0)}^l = \frac{1}{2} \delta_D = \gamma_j. \quad (C.13)$$

Then the result up to $\mathcal{O}(0)$ is

$$K_{(0)} = d. \quad (C.14)$$

Inserting this result into Eq. (C.6) or (C.7) one arrives at the well known cosmological con-
stant

$$\Lambda = \frac{d(d-1)}{2}. \quad (C.15)$$

We have used in Eq. (C.7) that $K_{(0)}^i = \delta_D K_{(0)}^i = 0$. The result for $K_{(2)}$ follows immediately from Eqs. (C.8) and (C.14),

$$K_{(2)} := P = \frac{\hat{R}}{2(d-1)}. \quad (C.16)$$
In order to proceed with the computation of $K^{(2)}_{j}^i$ from Eq. (C.9), we should evaluate first $\dot{K}_{j(2)}^i$. Using the definition of $d/dr$ given by Eq. (C.12), it writes

$$\dot{K}_{j(2)}^i = 2 \int d^4 x K_{(0)}^l m \frac{\delta}{\delta y^l} K_{(2)}^i j + 2 \int d^4 x K_{(2)}^l m \frac{\delta}{\delta y^l} K_{(0)}^i j$$

$$= 2 \int d^4 x \frac{\delta}{\delta y^l} K_{(2)}^i j = \delta_D K_{(2)}^i j = -2 K_{(2)}^i j. \quad (C.17)$$

Because $K_{(0)}^i j$ is the Kronecker’s delta, the second term after the first equality is zero, while the first one becomes the dilatation operator acting over $K_{(2)}^i j$. Then one gets from Eq. (C.9) the result

$$K_{(2)}^i j := P_j^i = \frac{1}{(d-2)} \left[ \delta_D^i j - P \delta_D^i j \right]. \quad (C.18)$$

Note that the trace of $K_{(2)}^i j$ agrees with Eq. (C.16). Using all the results above it is straightforward to solve for orders $O(4)$ and $O(\hat{4})$. From Eqs. (C.10) and (C.11) one gets respectively

$$K_{(4)} = \frac{1}{2(d-1)} \left[ P_j^i P_j^i - P^2 - \frac{1}{4} \Phi_{(0)}^i j \Phi_{(0)}^i j \right], \quad (C.19)$$

$$\dot{K}_{(4)} = 0. \quad (C.20)$$

In order to compute the counterterm for the on-shell action, besides the equations of motion an additional equation is needed. Following Ref. [90], one can introduce a covariant variable $\theta$ and write the on-shell action as

$$S_{on-shell} = \frac{1}{8 \pi G} \int d^4 x \sqrt{-h(K - \theta)}. \quad (C.21)$$

Then computing $\dot{S}_{on-shell}$ from Eq. (C.21), and comparing it with the result obtained by using Eqs. (7.24)-(7.26), one gets the following equation

$$0 = \dot{\theta} + K \theta - \frac{1}{(d-1)} \left( 2 \Lambda + \frac{1}{2} E_i E^i + \frac{1}{4} \Phi_{ij} \Phi^{ij} \right) - \frac{2}{3} \kappa \epsilon^{ijkl} A_i \Phi_{jkl} + \frac{12 \lambda}{(d-1)} \epsilon^{ijkl} A_i \Phi_{mkl} D_n K_{j}^m + E_i K_{jm} D_k K_{l}^m + \frac{1}{2} \Phi_{ik} K_{jm} \dot{K}_{kl}^m \right]. \quad (C.22)$$

The variable $\theta$ admits also an expansion in eigenfunctions of $\delta_D$ of the form

$$\theta = \theta_{(0)} + \theta_{(2)} + \theta_{(4)} + \tilde{\theta}_{(4)} \log e^{-2r} + \cdots, \quad (C.23)$$

where

$$\delta_D \theta_{(0)} = 0, \quad \delta_D \theta_{(2)} = -2 \theta_{(2)},$$

$$\delta_D \theta_{(4)} = -4 \theta_{(4)} - 2 \tilde{\theta}_{(4)}, \quad \delta_D \tilde{\theta}_{(4)} = -4 \tilde{\theta}_{(4)}. \quad (C.24)$$
Inserting expansion (C.23) into Eq. (C.22), one gets the following identities

\[ 0 = \hat{\theta}_1 + K_{(0)} \theta_{(0)} - \frac{2 \Lambda}{(d - 1)}, \quad (C.25) \]
\[ 0 = \hat{\theta}_{(2)} + K_{(2)} \theta_{(0)} + K_{(0)} \theta_{(2)}, \quad (C.26) \]
\[ 0 = \hat{\theta}_{(4)} + K_{(4)} \theta_{(0)} + K_{(2)} \theta_{(2)} + K_{(0)} \theta_{(4)} - \frac{1}{4(d - 1)} \hat{F}_{(0)}^{ij} \hat{F}_{(0)}^{ij}, \quad (C.27) \]
\[ 0 = \hat{\theta}_{(4)} + (\theta_{(0)} \hat{K}_{(4)} + K_{(0)} \theta_{(4)}) \log e^{-2r}, \quad (C.28) \]

corresponding to orders \( O(0), O(2), O(4) \) and \( O(4) \) respectively. Following the same procedure as shown in Eqs. (C.13) and (C.17), one gets

\[ \theta_{(0)} = 0, \quad \theta_{(2)} = \delta_D \theta_{(2)} = -2 \theta_{(2)}. \quad (C.29) \]

At this point one can solve Eqs. (C.25) and (C.26) to get

\[ \theta_{(0)} = 1, \quad \theta_{(2)} = \frac{P}{(2 - d)}. \quad (C.30) \]

Higher orders are a little bit more involved. Using the definition of \( d/dr \), then \( \hat{\theta}_{(4)} \) writes

\[
\begin{align*}
\hat{\theta}_{(4)} & = 2 \int d^4x K_{(0)}^I \gamma_{k} \frac{\delta}{\delta \gamma_{km}} \theta_{(4)} + 2 \int d^4x K_{(2)}^I \gamma_{k} \frac{\delta}{\delta \gamma_{km}} \theta_{(0)} + 2 \int d^4x K_{(4)}^I \gamma_{k} \frac{\delta}{\delta \gamma_{km}} \theta_{(2)} \\
& = \delta_D \theta_{(4)} + \frac{2}{(2 - d)} \int d^4x P_{km} \frac{\delta}{\delta \gamma_{km}} P.
\end{align*}
\]

(C.31)

Note that the second term after the first equality vanishes, while the first one writes in terms of \( \delta_D \). To evaluate the last term at the r.h.s. of eq. (C.31) we use

\[ \delta R = - \hat{R}^{km} \delta \gamma_{km} + D^k D^m \delta \gamma_{km} - \gamma^{km} D_i D^i \delta \gamma_{km}. \quad (C.32) \]

After a straightforward computation, one gets

\[ \hat{\theta}_{(4)} = -4 \theta_{(0)} - 2 \hat{\theta}_{(2)} + \frac{1}{(d - 1)(d - 2)} \left[ (d - 2) P_{j}^{i} P_{j}^{i} + P^2 + D_i (D^i P - D^i P_{j}^{j}) \right]. \quad (C.33) \]

Inserting Eq. (C.33) into Eq. (C.27) one can solve the latter, and the result is \(^1\)

\[ \hat{\theta}_{(4)} = \frac{1}{4} \left[ P_{j}^{i} P_{j}^{i} - P^2 - \frac{1}{4} \hat{F}_{(0)}^{ij} \hat{F}_{(0)}^{ij} + \frac{1}{3} D_j (D^j P - D^j P_{j}^{j}) \right]. \quad (C.34) \]

\(^1\) This result for \( \hat{\theta}_{(4)} \) includes a total derivative term which has not been computed in Ref. [90]. To compute \( \hat{\theta}_{(4)} \), in this reference the authors derive the elegant relation \( \hat{\theta}_{(4)} = \frac{(d - 1)}{2} K_{(4)} + \hat{\theta}_{(4)} \). This identity is however valid modulo total derivative terms.
The computation of $\dot{\theta}|_{(\bar{4})}$ follows in a similar way, and one gets $\dot{\theta}|_{(\bar{4})} = -4\bar{\theta}_{(4)} \log e^{-2r}$. By inserting it into Eq. (C.28), this equation is trivially fulfilled.

The counterterm of the action can be read out from Eq. (C.21) by using $K$ and $\theta$ computed up to order $O(\bar{4})$, i.e.

$$S_{ct} = S_{on-shell} = -\frac{1}{8\pi G} \int_\partial d^4x \sqrt{-h} \left[ (K_0 - \theta_0) + (K_2 - \theta_2) + (K_{(4)} - \bar{\theta}_{(4)}) \log e^{-2r} \right].$$

From this equation and Eqs. (C.14), (C.16), (C.20), (C.30) and (C.34), one finally gets

$$S_{ct} = -\frac{(d-1)}{8\pi G} \int_\partial d^4x \sqrt{-h} \left[ 1 + \frac{1}{(d-2)} P - \frac{1}{4(d-1)} \left( P^i P_i^j - P^2 - \frac{1}{4} \hat{F}_0^{ij} \hat{F}_0^{ij} \right) \log e^{-2r} \right].$$

(C.36)

The last term in Eq. (C.34) is a total derivative, and so it doesn’t contribute to the action. As a remarkable fact we find that there is no contribution in the counterterm coming from the gauge-gravitational Chern-Simons term. This is because this term only contributes at higher orders. Indeed as explained above, in the renormalization procedure we use Eqs. (B.3) and (C.22) up to orders $O(0)$, $O(2)$, $O(4)$ and $O(\bar{4})$, and Eq. (B.2) up to orders $O(0)$ and $O(\bar{4})$. We have explicitly checked that the $\lambda$ dependence starts contributing at $O(6)$ in all these three equations. This means that the gauge-gravitational Chern-Simons term does not induce new divergences, and so the renormalization is not modified by it.

---

Note that $K^i_j$ and $\theta$ induce terms proportional to $\lambda$. Up to order $O(4) + O(\bar{4})$ these operators write $K^i_j|_{(4)+\bar{4}} = -4K_{(4)}^{i} + \ldots$ and $\theta|_{(4)+\bar{4}} = -4\theta_{(4)} + \ldots$, where the dots indicate extra terms which are $\lambda$-independent. The only $\lambda$-dependence could appear in $K_{(4)}^{i}$ and $\theta_{(4)}$, but these contributions are precisely cancelled by other terms in Eqs. (B.2) and (C.22) respectively, so that these equations become $\lambda$-dependent only at $O(6)$ and higher.
The perturbative solutions of the system (7.47) and (7.48) up to first order in momentum are

These are the complete linearized set of six dynamical equations of motion

\[ 0 = B_\alpha''(u) + \frac{f'(u)}{f(u)} B_\alpha'(u) + \frac{b^2}{uf(u)^2} \left( w^2 - f(u)k^2 \right) B_\alpha(u) - \frac{h_\alpha'(u)}{f(u)} \]

\[ + ik\varepsilon_{\alpha\beta} \left( \frac{3}{uf(u)} \tilde{\lambda} \left( \frac{2}{3a} (f(u) - 1) + u^3 \right) h_\beta'(u) + \tilde{\kappa} \frac{B_\beta(u)}{f(u)} \right), \]  

(D.1)

\[ 0 = h_\alpha''(u) - \frac{h_\alpha'(u)}{u} - \frac{b^2}{uf(u)} \left( k^2 h_\alpha'(u) + h_\alpha''(u)wk - 3auB_\alpha'(u) \right) \]

\[ + 2u(uh_\beta'(u)' - 2ub^2 \left( h_\beta'(u)wk + h_\beta'(u)k^2 \right) \tilde{\lambda} k\varepsilon_{\alpha\beta} \left( 24au^3 - 6(1 - f(u)) \right) \frac{B_\beta(u)}{u} + (9au^3 - 6(1 - f(u))) B_\beta' \]

\[ + 2u(uh_\beta'(u))' + 2ub^2 \frac{h_\beta'(u)wk + h_\beta'(u)k^2}{f(u)}, \]  

(D.2)

\[ 0 = h_\beta''(u) + \frac{(f/u)'}{f/u} h_\beta'(u) + \frac{b^2}{uf(u)^2} \left( w^2 h_\beta'(u) + wh_\beta'(u) + 2uik\tilde{\lambda} \varepsilon_{\alpha\beta} \left( uh_\gamma'(u) \right) \right) \]

\[ + (9f(u) - 6 + 3au^3) \frac{h_\beta'(u)}{f(u)} + \frac{b^2}{f(u)^2} \left( wh_\beta'(u) + w^2 h_\beta'(u) \right) \]  

(D.3)

and two constraints for the fluctuations at \( w, k \neq 0 \)

\[ 0 = w \left( h_\alpha'(u) - 3auB_\alpha'(u) \right) + f(u)kh_\alpha'(u) + ik\tilde{\lambda} \varepsilon_{\alpha\beta} \left[ 2u^2 \left( wh_\beta' + f(u)kh_\beta'(u) \right) \right] \]

\[ + (9au^3 - 6(1 - f(u))) B_\beta(u), \]  

(D.4)
Equation of motion for shear sector
We write in this appendix the solutions for the system (7.47)-(7.48). These functions depend explicitly on the boundary sources $\tilde{H}^\alpha$ and $\tilde{B}_\alpha$, and the anomalous parameters $\bar{\kappa}, \bar{\lambda}$. Switching off $\bar{\lambda}$ we get the same system obtained in [36]

\[
\begin{align*}
    h_\alpha^\alpha(u) &= \tilde{H}^\alpha f(u) - \frac{ik\tilde{\kappa}_\alpha^\beta(u - 1)a}{2(1 + 4a)} \left[ (1 + 4a)^{3/2}u^2 \tilde{R}_\beta^\beta + \right. \\
    &\hspace{1cm} - 3 \left( \sqrt{1 + 4au(2au - 1)} + 2(1 + u - au^2) \right) \text{ArcCoth} \left( \frac{2 + u}{1 + 4au} \right) \left. \tilde{B}_\beta \right| \] \\
    \hspace{1cm} &\hspace{1cm} + ki\bar{\lambda} \varepsilon_{\alpha\beta}(u - 1) \left[ \tilde{B}_\beta \left( - \frac{3i(u + 1)(1 + a)\pi}{2a} + \frac{3(1 + a(5 + a))u}{(1 + 4a)} + \frac{(5 + 21a + 2a^2)u^2}{(1 + 4a)} \right) \\
    \hspace{1cm} &\hspace{1cm} + \frac{3}{2} \left( 1 + a \right) \pi u^2 - 6au^3 - \frac{3if(u)(1 + a(7 + 2a(7 + a)))\text{ArcCoth} \left( \frac{2 + u}{(1 + 4au)} \right)}{(u - 1)(-1 - 4a)^{3/2}} \right. \\
    \hspace{1cm} &\hspace{1cm} \left. - \frac{3f(u)(1 + a)}{2a(u - 1)} \text{Log} \left[ -1 - u + au^2 \right] \right] \\
    \hspace{1cm} &\hspace{1cm} + \frac{2i(u + 1)(1 + a)^2 \pi}{a^2} + \frac{2(1 + a)(2 + a(7 + 2a))u}{a(1 + 4a)} \\
    \hspace{1cm} &\hspace{1cm} + \frac{(4 + a(25 + a(39 + a(-5 + 4a))))u^2}{a(1 + 4a)} + \frac{2i(1 + a)^2\pi u^2}{a} \\
    \hspace{1cm} &\hspace{1cm} u^3(1 - 5a - 6au) + \\
    \hspace{1cm} &\hspace{1cm} - \frac{4if(u)(1 + a)(1 + 2a)(1 + a(5 + a))\text{ArcCoth} \left( \frac{2 + u}{(1 + 4au)} \right)}{(u - 1)(-1 - 4a)^{3/2}a^2} \\
    \hspace{1cm} &\hspace{1cm} - \frac{2f(u)(1 + a)^2\text{Log} \left[ -1 - u + au^2 \right]}{(u - 1)a^2} \right] ,
\end{align*}
\]
\begin{align*}
B_\alpha (u) = & \quad B_\alpha + \mathcal{B}^\alpha u - i \frac{k \varepsilon_{\alpha \beta}}{2(1+4a)^{3/2}} \left( \mathcal{B}^\beta u (1 + 4a)^{3/2} + \right. \\
& \left. \mathcal{B}_\beta \left( 6a \sqrt{1 + 4au} - 2(-2 + a(-2 + 3u)) \text{ArcCoth} \left[ \frac{2 + u}{\sqrt{1 + 4au}} \right] \right) ight) \\
& + i \tilde{\lambda} \varepsilon_{\alpha \beta} \left[ \mathcal{B}_\beta \left( -\frac{i(1 + a)^2 \pi}{a^2} + \frac{2(1 + a)(1 + a(5 + a))u}{a(1 + 4a)} + \frac{3i(1 + a)\pi u}{2a} ight) ight. \\
& \left. -3u^3 - \frac{i(1 + a(7 + 2a(7 + a)))(-2 + a(-2 + 3u))\text{ArcCoth} \left[ \frac{2 + u}{\sqrt{1 + 4au}} \right]}{2a^2} ight) \\
& - (1 + a)(-2 + a(-2 + 3u))\text{Log} \left[ -1 + u + au^2 \right] \\
& + \mathcal{B}^\beta \left( -\frac{4i(1 + a)^3 \pi}{3a^3} + \frac{8 + a(48 + a(84 + a(29 + 12a)))u}{3a^5(1 + 4a)} \right) \\
& + \frac{2i(1 + a)^2 \pi u}{a^2} - \frac{2(1 + a)u^2}{a} - 3u^3 \\
& - \frac{4i(1 + a)(1 + 2a)(1 + a(5 + a))(-2 + a(-2 + 3u))\text{ArcCoth} \left[ \frac{2 + u}{\sqrt{1 + 4au}} \right]}{3(-1 - 4a)^{3/2}a^3} \\
& - \frac{2(1 + a)^2(-2 + a(-2 + 3u))\text{Log} \left[ -1 + u + au^2 \right]}{3a^3} \right].
\end{align*}
We have seen that in the hydrodynamic regime the velocity of the fluid in the Landau frame is determined modulo a $P$-odd term $v_m \sim O(k)$ that is an arbitrary function of the sources. In this appendix we show the independence of the transport coefficients on this arbitrary function, even if the correlators are velocity dependent, and also that these arbitrariness disappears once we correctly impose the physical boundary conditions on the bulk fields. For simplicity we will do this analysis in the case when the mixed-gravitational anomaly vanish.

In order to do so, we are going to solve the system at $\omega = 0$, first order in $k$ and for arbitrary value of $v_m$. Again, the system reduces to:

\begin{align}
0 &= h_i''(u) - \frac{h_i'(u)}{u} - 3auB'_i(u), \quad (F.1) \\
0 &= B_i(u) + \frac{f'(u)}{f(u)} B'_i(u) - i\varepsilon_{ij} \kappa \frac{kB_j(u)}{f(u)} - \frac{h_i'(u)}{f(u)}, \quad (F.2)
\end{align}

where $h_i'(u) = h_i^{(0)}(u) + p h_i^{(1)}(u)$ and $B_i(u) = B_i^{(0)}(u) + p B_i^{(1)}(u)$. After imposing regularity at the horizon we find the following solutions:

\begin{align}
B_i^{(0)}(u) &= \tilde{B}_i + A_i u, \quad (F.3) \\
B_i^{(1)}(u) &= C_i u - \frac{2i(1+a)^2 \kappa \varepsilon_{ij} A_j u}{(2-a)(1+4a)b} - \frac{i \kappa \varepsilon_{ij} \tilde{B}_j}{(2-a)(1+4a)^{3/2}b} \left(9a(1+a)u\sqrt{1+4a} \right) 
+ (2-a)^2 \left(2(1+a)\text{ArcCoth} \left[\sqrt{1+4a}\right] + (2+a(2-3u))\text{ArcTanh} \left[\frac{-1+2au}{\sqrt{1+4a}}\right] \right) \quad (F.4)
\end{align}
\[ h^{(0)}_i(u) = \tilde{h}_i + A_i(f(u) - 1), \]  
\[ h^{(1)}_i(u) = C_i(f(u) - 1) - \frac{ia \tilde{k}(4(1+a)^2u - 27a) \epsilon_{ij} A_j u^2}{2(2-a)(1+4a)b} \]  
\[ + \frac{3ia \tilde{k} \epsilon_{ij} \tilde{B}_j}{2(2-a)(1+4a)^{3/2}b} \left((2+a(16+5a))u - 6a(1+a)u^2 - (2-a)^2\sqrt{1+4au}\right) \]  
\[ + 2(2-a)^2 \left(\text{ArcCot} \left[\sqrt{1+4a} \right] + f(u) \text{ArcTanh} \left[\frac{1+2au}{\sqrt{1+4a}}\right]\right) . \]

As we know, this is not enough to solve the boundary value problem since both of the two independent solutions for the metric fluctuations satisfy the regularity condition. However, we can use the constitutive relations to try to fix the arbitrariness. In the hydrodynamic description, the stress-energy tensor is given by

\[ T^{ii} = (\epsilon + P)v^i - P \tilde{h}^{ii} , \]  
where the velocity is order \( p \). Using the holographic dictionary, we can identify the coefficient of the non-normalizable mode of the asymptotic behavior of a bulk field with the source of the dual operator and the coefficient of the normalizable one with its expectation value. Therefore, we can write the metric fluctuation close to the boundary as

\[ h_i^*(u) \sim \tilde{h}_i^* + T^i_i u^2 , \]  
so using the hydrodynamic result, we can do the identification order by order in momentum, in such a way that the velocity piece of the energy tensor fixes the horizon value of \( h^{(1)}_i \). Doing so, the asymptotic behavior of each order becomes

\[ h^{(0)}_i(u) \sim \tilde{h}_i^*(1 - Pu^2) , \]  
\[ ph^{(1)}_i(u) \sim -(\epsilon + P)v_i u^2 . \]  

We can proceed to construct the matrix of correlators for arbitrary value of the velocity as explained in Chapter 7. Now, all the correlators pick contributions proportional to the velocity. In a compact way, the retarded propagators read

\[ G_{i,j} = -\frac{r_H}{\pi GL} \left(\frac{iv\sqrt{3}a k(4+a)\kappa}{8(1+a)} \epsilon_{ij} - \frac{r_H}{2L^2} \frac{\partial v_i}{\partial \tilde{B}_j}\right) - \frac{ik\beta\kappa}{6\pi G} \epsilon_{ij} , \]  
\[ G_{i,k} = -\frac{r^2_H}{\pi GL^2} \left(\frac{3ia k \kappa}{4(1+a)} \epsilon_{ij} - \frac{\sqrt{3}a r_H}{4L} \delta_{ij} - \frac{\sqrt{3}a r_H}{2L^2} \frac{\partial v_i}{\partial h_j}\right) , \]  
\[ G_{ii} = \frac{r^3_H}{\pi GL^3} (1+a) \frac{\partial v_i}{\partial \tilde{B}_j} , \]  
\[ G_{ii,j} = \frac{r^4_H}{\pi GL^5} \left(\frac{1+a}{16} \delta_{ij} + (1+a) \frac{\partial v_i}{\partial h_j}\right) . \]
where $i, j = x, z$. It is straightforward to prove that applying definitions (4.83) and (4.82) for the chiral vortical and magnetic conductivities, the result is independent of the velocity and coincides with (7.64) and (7.63) as expected. Setting the velocities to zero, the correlators coincide with those presented in [108].

If we now impose the correct zero frequency ‘infalling’ condition to the fields $h_i^j$, i.e. vanishing at the horizon, the velocities are not arbitrary anymore, but are given in terms of the boundary sources,

$$v_i = -\frac{ia\tilde{\kappa}\epsilon_{ij}(2\tilde{h}_j + 3\tilde{B}_j)k}{16(1+a)}.$$  

(Of course, substituting them in the Green functions given above, the antisymmetric correlation matrix spanned by (7.55) – (7.59) is recovered.)
APPENDIX G

COMPARING THE $\lambda$ AND $\kappa$ CONTRIBUTION IN THE FREQUENCY DEPENDENCE

Figure G.1: Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency at $\tau = 36.5$ (left) and $\tau = 0.24$ (right). Red doted points represent real part and blue line the imaginary conductivity. Small dots and thin lines represent the conductivities with $\lambda = 0$ and the thick case shows the $\kappa = 0$ case. All cases are normalized to zero frequency conductivities with both anomalous parameters switched on.
Comparing the $\lambda$ and $\kappa$ contribution in the frequency dependence

Figure G.2: Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency close to $\omega = 0$. Real (left) and imaginary (right) part of the normalized conductivity for different values of the dimensionless temperature.
Here we show the exact form of the $F_1[\rho]$ functions defined in Eqs. (8.49) and (8.51)

\[
F_1[\rho] = -Q\left(\frac{(9Q^6\rho^2 + 2M^2\rho^4)(-4M + 3(1 + M)\rho) - 27Q^4(1 + M - \rho^2) + 6Q^2(4M^2 + 3\rho - 6\rho^4))\rho_2(2 + 5\rho^2 + 2\rho^3)}{8M^2\rho^4\rho_2(-1 + \rho^2)}\right)
\]

\[
+ \frac{-6\rho(1 - \rho^2)(\rho^2 - \rho_2)(-1 + \rho^2)}{8M^2\rho^4\rho_2(-1 + \rho^2)}\right) + \frac{3(Q^2 - M\rho^2 + \rho^6)\rho_2(-2 - 3\rho^2 + 3\rho_2^2 + 2\rho_2^3)\text{ArcTan}\left[\frac{\rho}{\sqrt{1 + \rho^2}}\right]}{2M(2 + \rho^4)^3(1 + 2\rho^3)}
\]

\[
\frac{3}{2} \frac{Q(Q^2 - M\rho^2 + \rho^6)(-1 + \rho_2)(2 + \rho_2^2)\text{Log}[\rho - \rho_2]}{4\rho^4(-1 + \rho_2)(1 + 2\rho_2^2)} - \frac{3Q(Q^2 - M\rho^2 + \rho^6)\rho_2(2 + \rho_2^2)}{4\rho^4(2 + \rho_2^2)(1 + 2\rho_2^2)}
\]

\[
(H.1)
\]

\[

First order solutions in the Fluid/Gravity approach
APPENDIX I
SECOND ORDER SOURCES

I.1 Second Order Vector Sources

In this appendix we show the vector sources splitted in terms of the anomalous and non anomalous one, the tildes refer to the anomalous sector

\[
\mathbb{J}_\mu = \sum_{a=1}^{10} r_a^{(E)} \partial_\mu \tilde{r}^{(a)} + \sum_{a=1}^{5} r_a^{(M)} \partial_\mu \tilde{r}^{(a)}, \quad \bar{\mathbb{A}}_\mu = \sum_{a=1}^{10} r_a^{(M)} \partial_\mu \tilde{r}^{(a)} + \sum_{a=1}^{5} r_a^{(M)} \partial_\mu \tilde{r}^{(a)},
\]

(I.1)

I.1.1 Non-anomalous sources

\[
\begin{align*}
\frac{4\pi T^2}{\sqrt{3}M(1+M)p^{1+f}|p|} \times \\
\text{constant factors} \times \frac{2\pi T^2 \rho_1 F_1[p]}{\sqrt{3}(1+M)p^{1+f}|p|} + \frac{2\pi T^2 \rho_1 F_1[p]}{\sqrt{3}(1+M)p^{1+f}|p|} - 4\pi T^2 (1+\rho_1 + \rho_2) F_1[p] \quad (I.2)
\end{align*}
\]

\[
\begin{align*}
\frac{4\pi T^2}{\sqrt{3}M(1+M)p^{1+f}|p|} \times \\
\text{constant factors} \times \frac{2\pi T^2 \rho_1 F_1[p]}{\sqrt{3}(1+M)p^{1+f}|p|} + \frac{2\pi T^2 \rho_1 F_1[p]}{\sqrt{3}(1+M)p^{1+f}|p|} - 4\pi T^2 (1+\rho_1 + \rho_2) F_1[p] \quad (I.3)
\end{align*}
\]
Second order sources

3.1 Two formalisms for the chemical potential . . . . . . . . . . . . . . . . . . . 14

4.1 Weyl weights for the chemical potential, temperature, fluid velocity, metric, pressure, charge density, electric field and magnetic field . . . . . . . . . . 28
3.1 At finite temperature field theories are defined on the Keldysh-Schwinger contour in the complexified time plane. The initial state at $t_i$ is specified through the boundary conditions on the fields. The endpoint of the contour is at $t_i - i\beta$ where $\beta = 1/T$.

4.1 $C, P$ properties of the first order scalars, vectors and tensors.

5.1 Contributions to the Kubo formula for the chiral magnetic conductivity in the different formalisms for the chemical potential.

5.2 A sketch of the Euclidean black hole topology. A singularity at the horizon arises if we do not choose the temporal component of the gauge field to vanish there. On the other hand allowing the singularity to be present changes the topology to the one of a cylinder and this in turn allows twisted boundary conditions.

6.1 The triangle diagram.

6.2 1 loop diagram contributing to the vortical conductivity Eq. (6.17).

7.1 Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency at $\tau = 36.5$ (left) and $\tau = 0.24$ (right). Red doted points represent real part and thick blue line the imaginary conductivity.

7.2 Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency close to $\omega = 0$. Real (left) and imaginary (right) part of the normalized conductivity for different values of the dimensionless temperature.

<tr>
<td>G.1</td>
<td>Chiral vortical (up) and magnetic (bottom) conductivities as function of the frequency at $\tau = 36.5$ (left) and $\tau = 0.24$ (right). Red doted points represent real part and blue line the imaginary conductivity. Small dots and thin lines represent the conductivities with $\lambda = 0$ and the thick case shows the $\kappa = 0$ case. All cases are normalized to zero frequency conductivities with both anomalous parameters switched on.</td>
